

# Introduction to LabVIEW Design Patterns

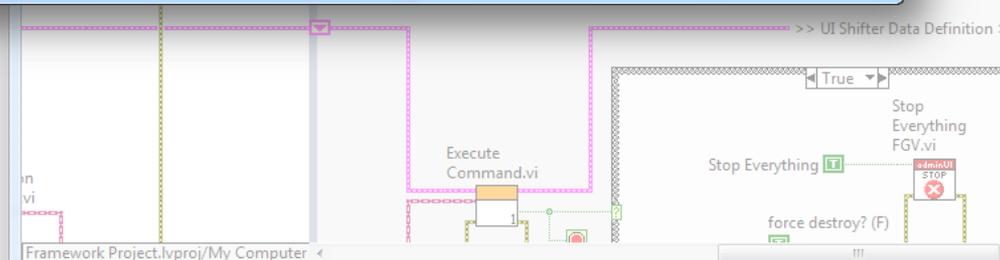

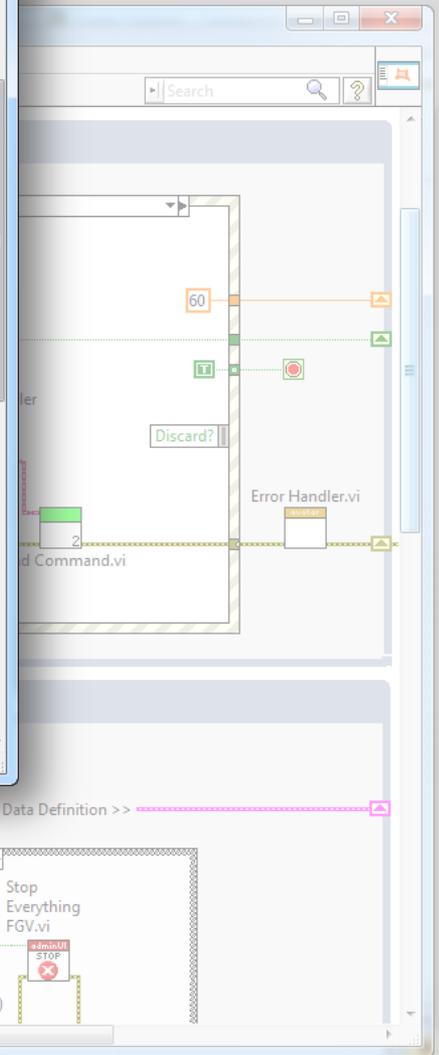

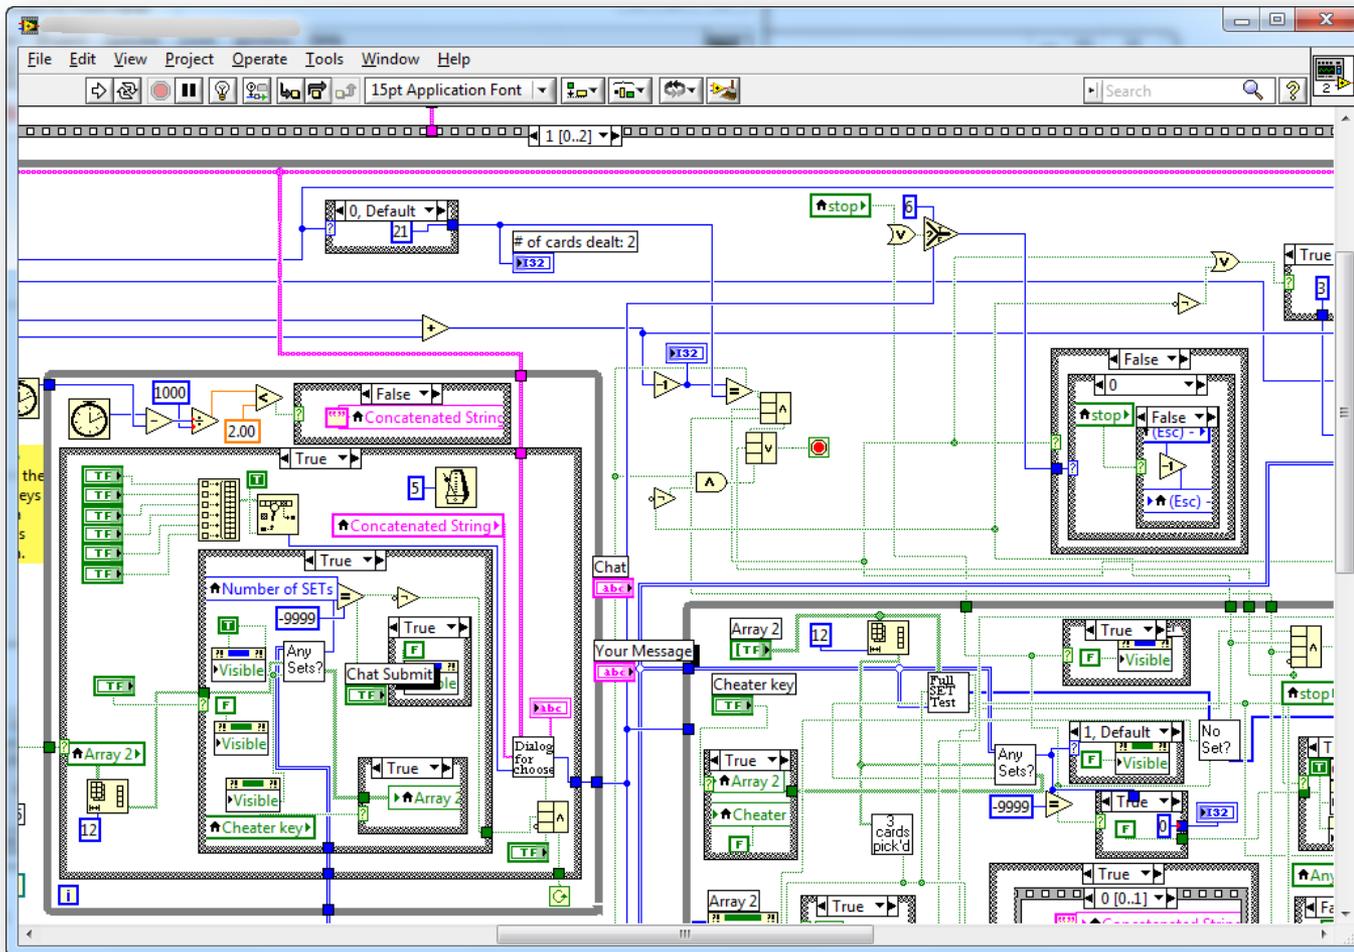

# What is a Design Pattern?

**Definition:** A well-established solution to a common problem.

# Why Should I Use One?

Save time and improve the longevity and readability of your code.

... or else...

# Examples of Software Engineering Debt

(just *some* of the most common LabVIEW development mistakes)

- ✓ No source code control (or Project)
- ✓ Flat file hierarchy
- ✓ 'Stop' isn't tested regularly
- ✓ Wait until the 'end' of a project to build an application
- ✓ Few specifications / documentation / requirements
- ✓ No 'buddying' or code reviews
- ✓ **Poor planning (Lack of consideration for SMoRES)**
- ✓ No test plans
- ✓ Poor error handling
- ✓ No consistent style
- ✓ Tight coupling, poor cohesion

# Designing for SMORES

Criteria for a well designed software application:

**Scalable:** how simple is  $N + 1$ ?

**Modular:** is the application broken up into well-defined components that stand on their own?

**Reusable:** is the code de-coupled from the current application well-enough such that it could be reused in a future project?

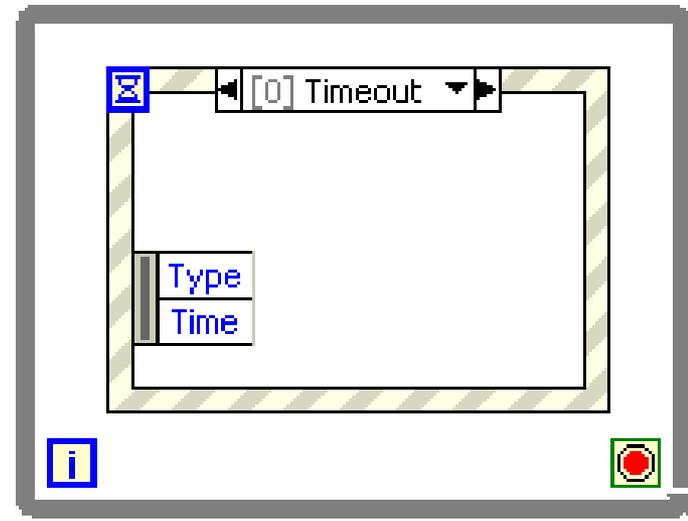

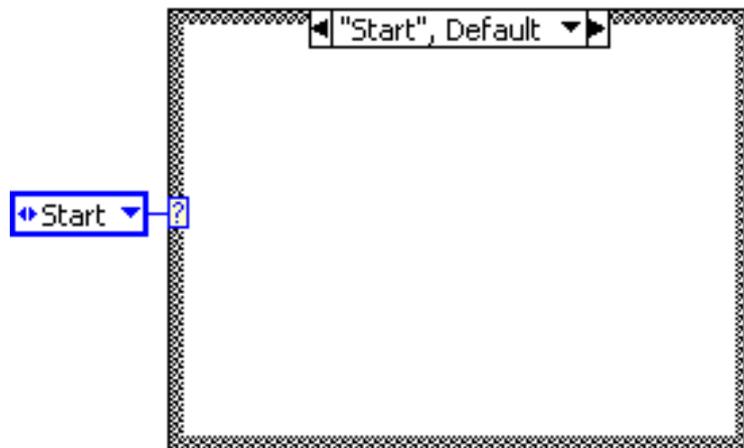

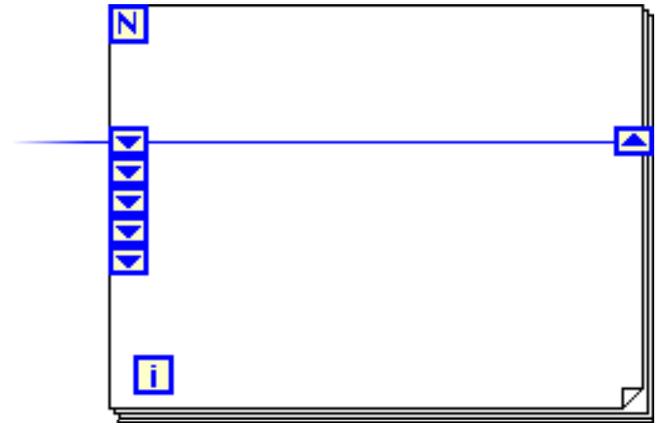

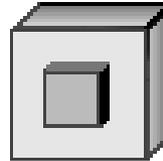

**Extensible:** how painful is it to add new functionality?

**Simple:** what is the simplest solution that satisfies all of the listed criteria and the requirements of the application?

# You Should Already Be Familiar With..

- Loops
- Shift Registers
- Case Structures
- Enumerated Constants
- Event Structures
- LabVIEW Classes

LabVIEW Object

# Design Patterns

- Functional Global Variable
- State Machine / Statecharts
- Event Driven User Interface
- Producer / Consumer
- Queued State Machine – Producer / Consumer

# Functional Global Variables

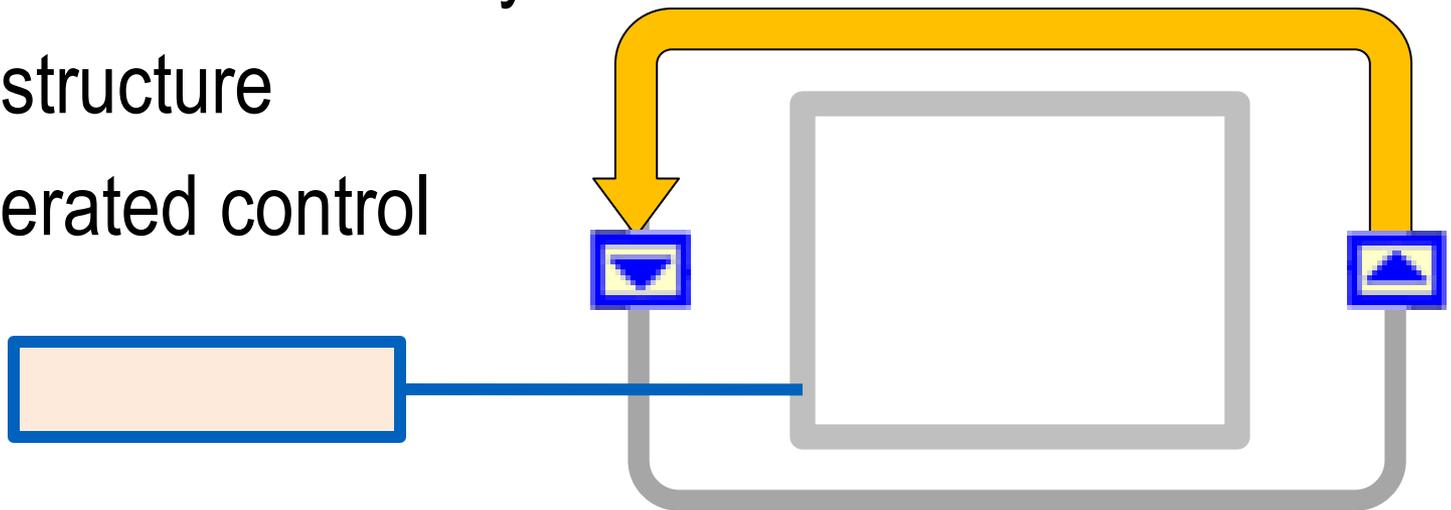

How do I share data across a application without using Global or Local Variables?

# Background: Global and Local Variables

- Can cause race conditions
- Create copies of data in memory
- Cannot perform actions on data
- Cannot handle error wires

# Breaking Down the Design Pattern

- While loop
- Uninitialized shift registers have memory
- Case structure
- Enumerated control

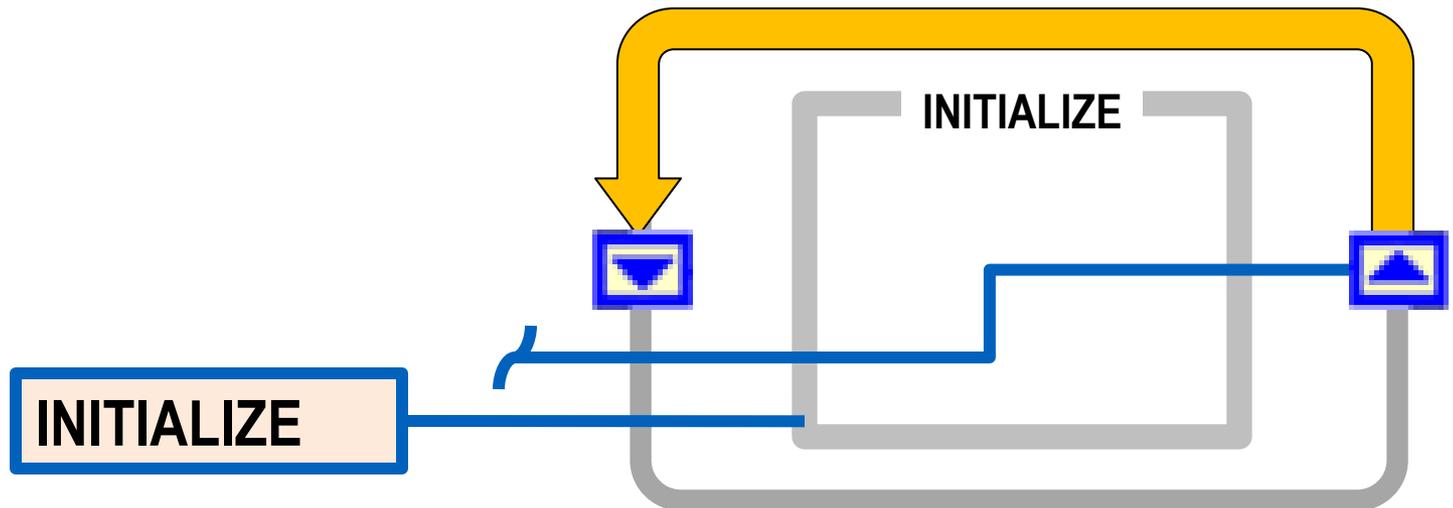

**Uninitialized Shift Registers**

**DEMO**

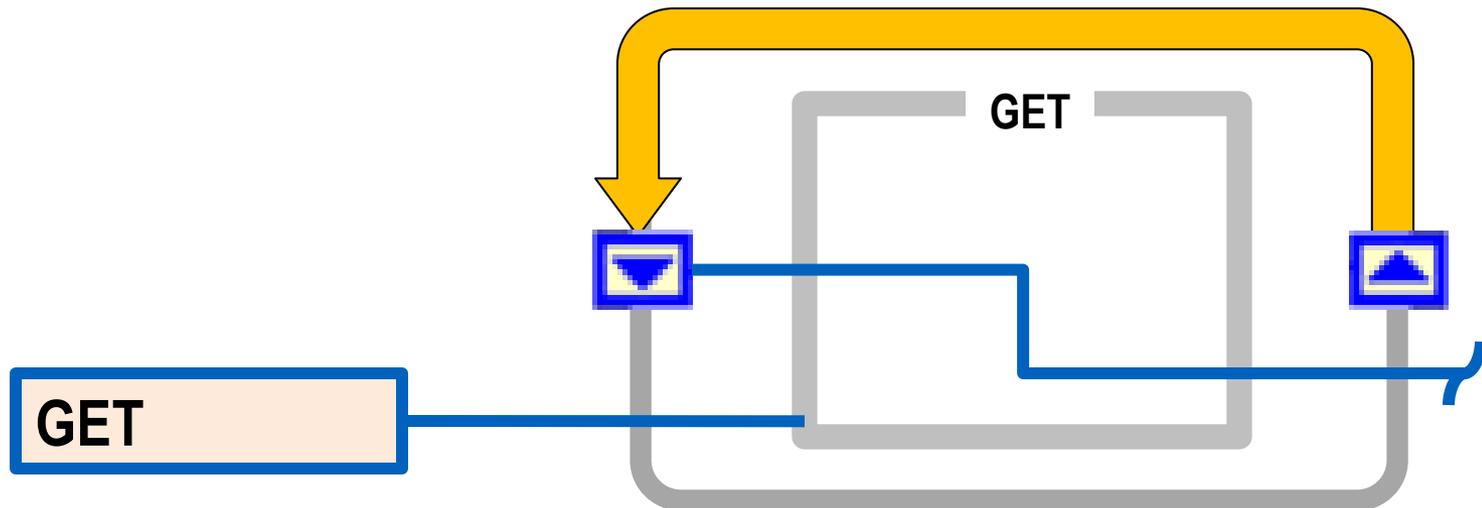

# Basic Actions

- Set the value of the shift register

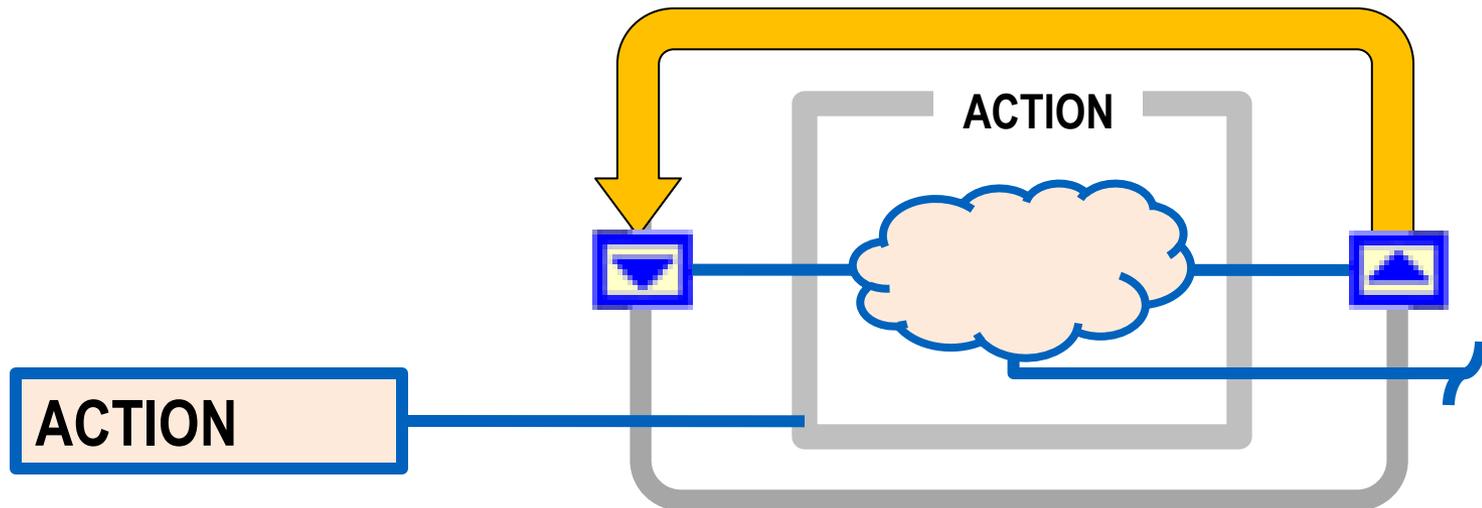

# Basic Actions

- Get the value currently stored in the shift register

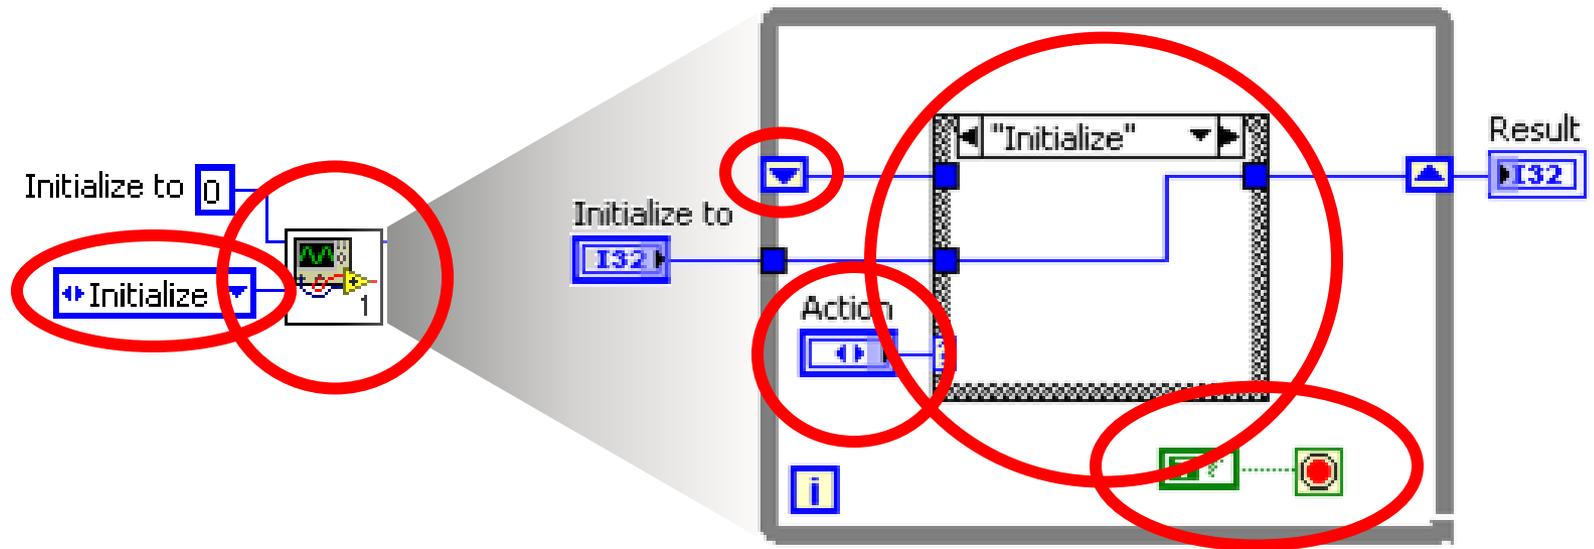

# Action Engine

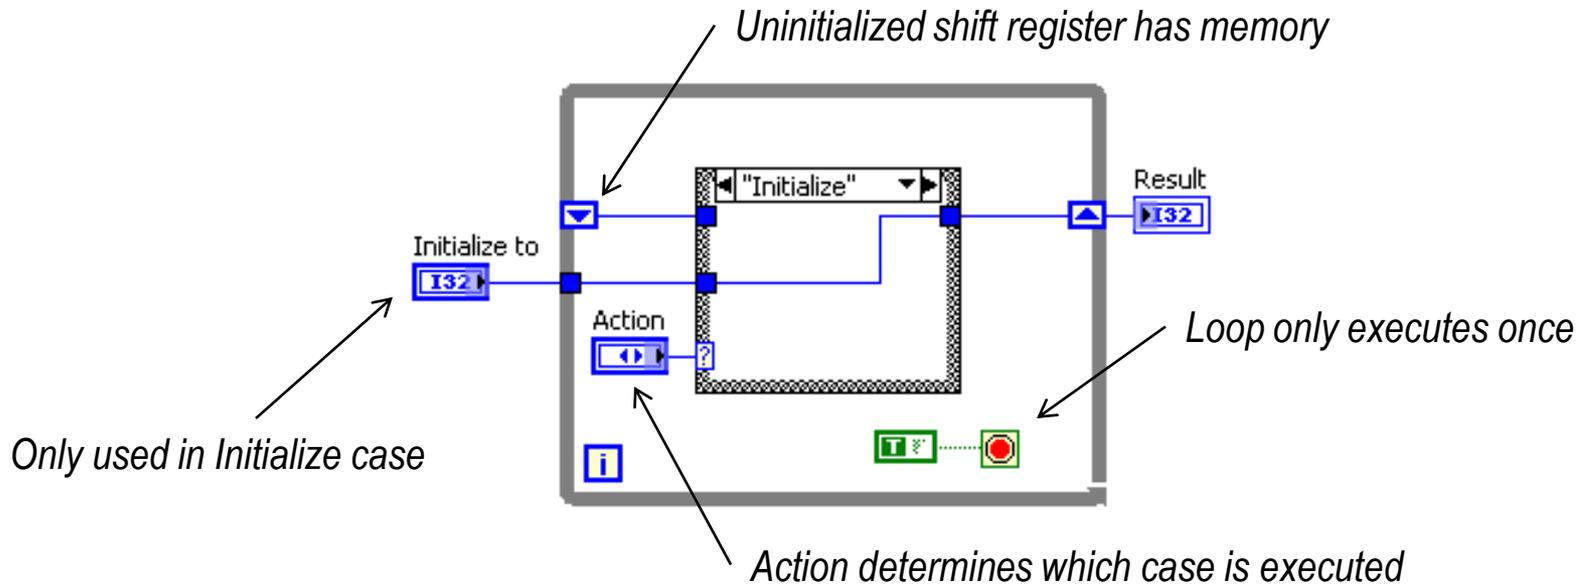

- Perform an operation upon stored value and save result
- You can also output the new value

# How It Works

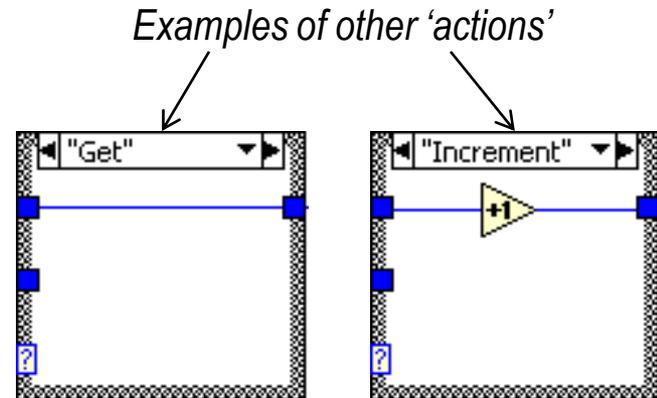

1. Functional Global Variable is a **Non-Reentrant** SubVI
2. Actions can be performed upon data
3. Enumerator selects action
4. Stores result in uninitialized shift register
5. Loop only executes once

## Functional Global Variables

# DEMO

# Benefits: Comparison

## Functional Global Variables

- Prevent race conditions
- No copies of data
- Can behave like action engines
- Can handle error wires
- Take time to make

## Global and Local Variables

- Can cause race conditions
- Create copies of data in memory
- Cannot perform actions on data
- Cannot handle error wires
- Drag and drop

# Recommendations

## Use Cases

- Communicate data between code without connecting wires
- Perform custom actions upon data while in storage

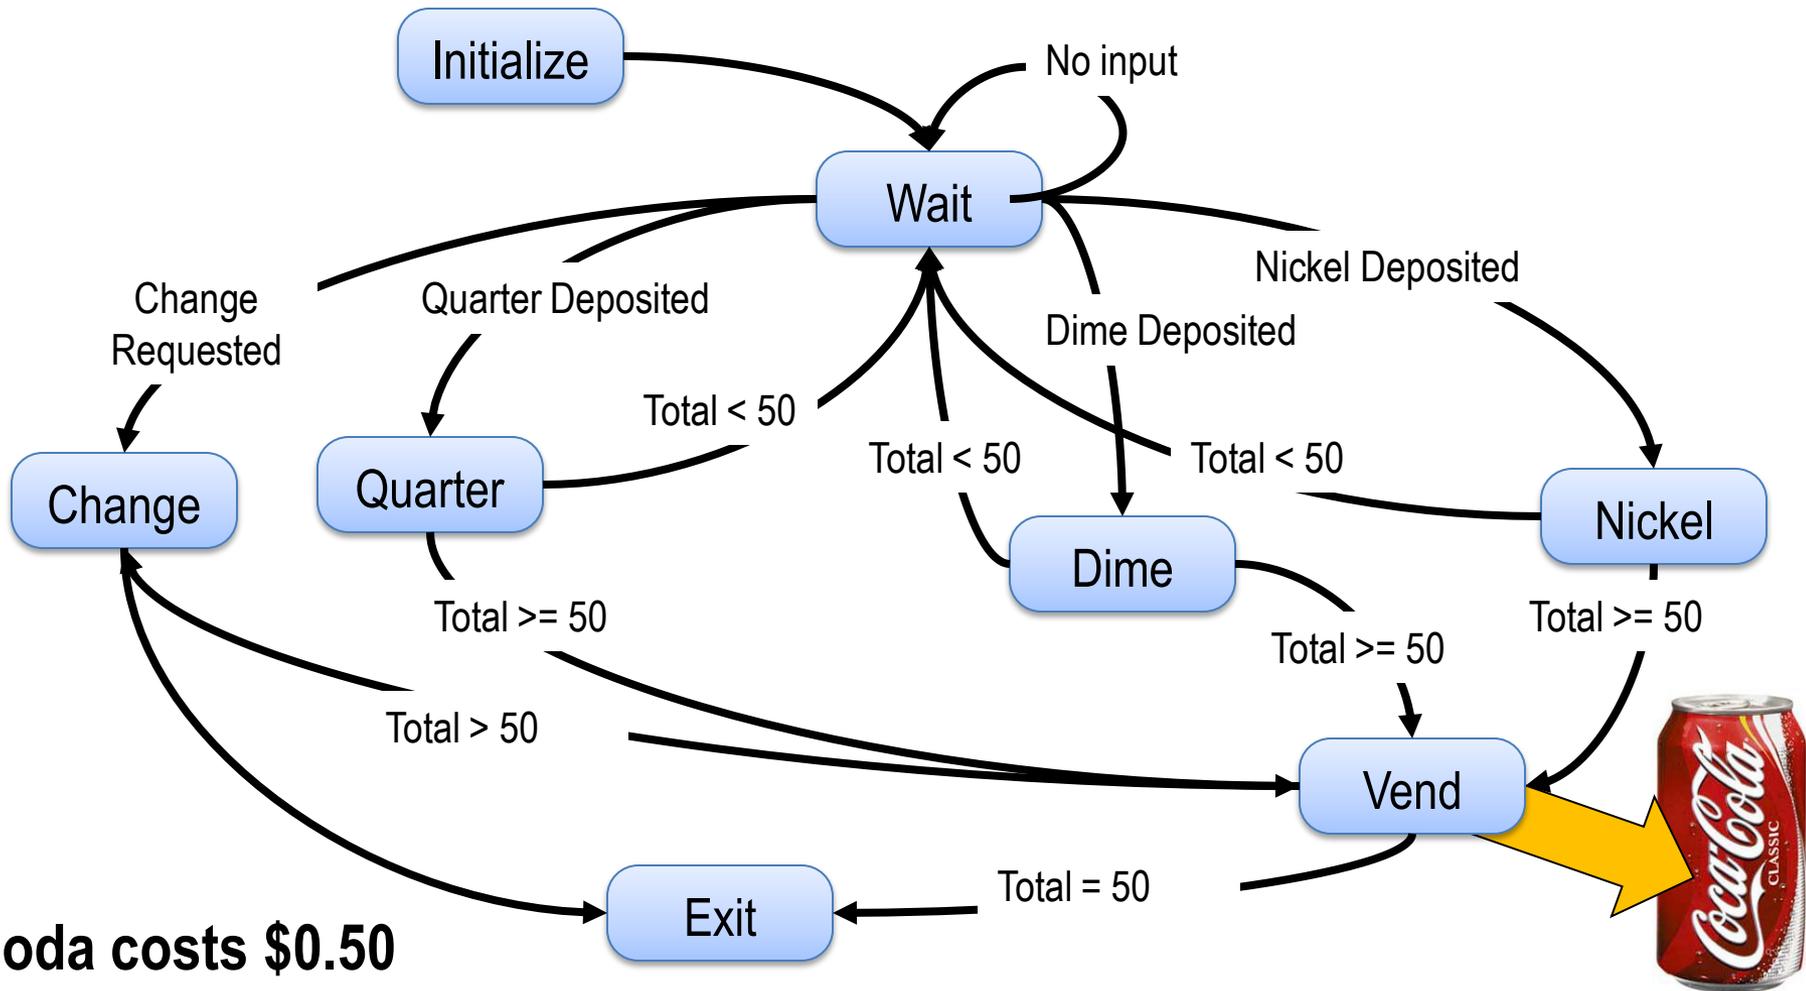

## Considerations

- All owning VIs must stay in memory
- Use clusters to reduce connector pane
- Using stacked shift registers will track multiple iterations

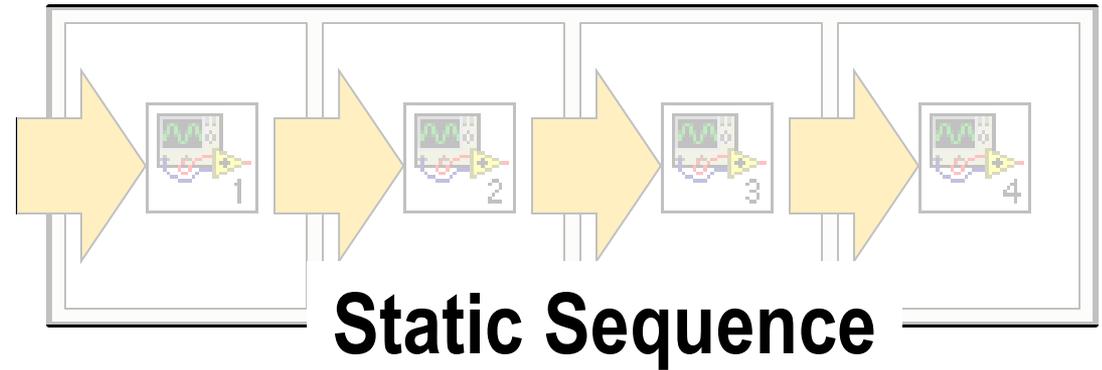

# State Machine

I need to execute a sequence of events, but the order is determined programmatically

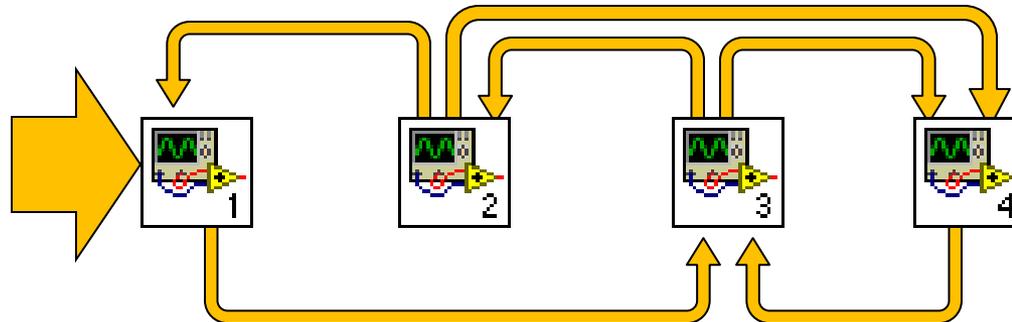

# Soda Machine

# Background

**Dynamic Sequence:** Allows distinct states to operate in a programmatically determined sequence

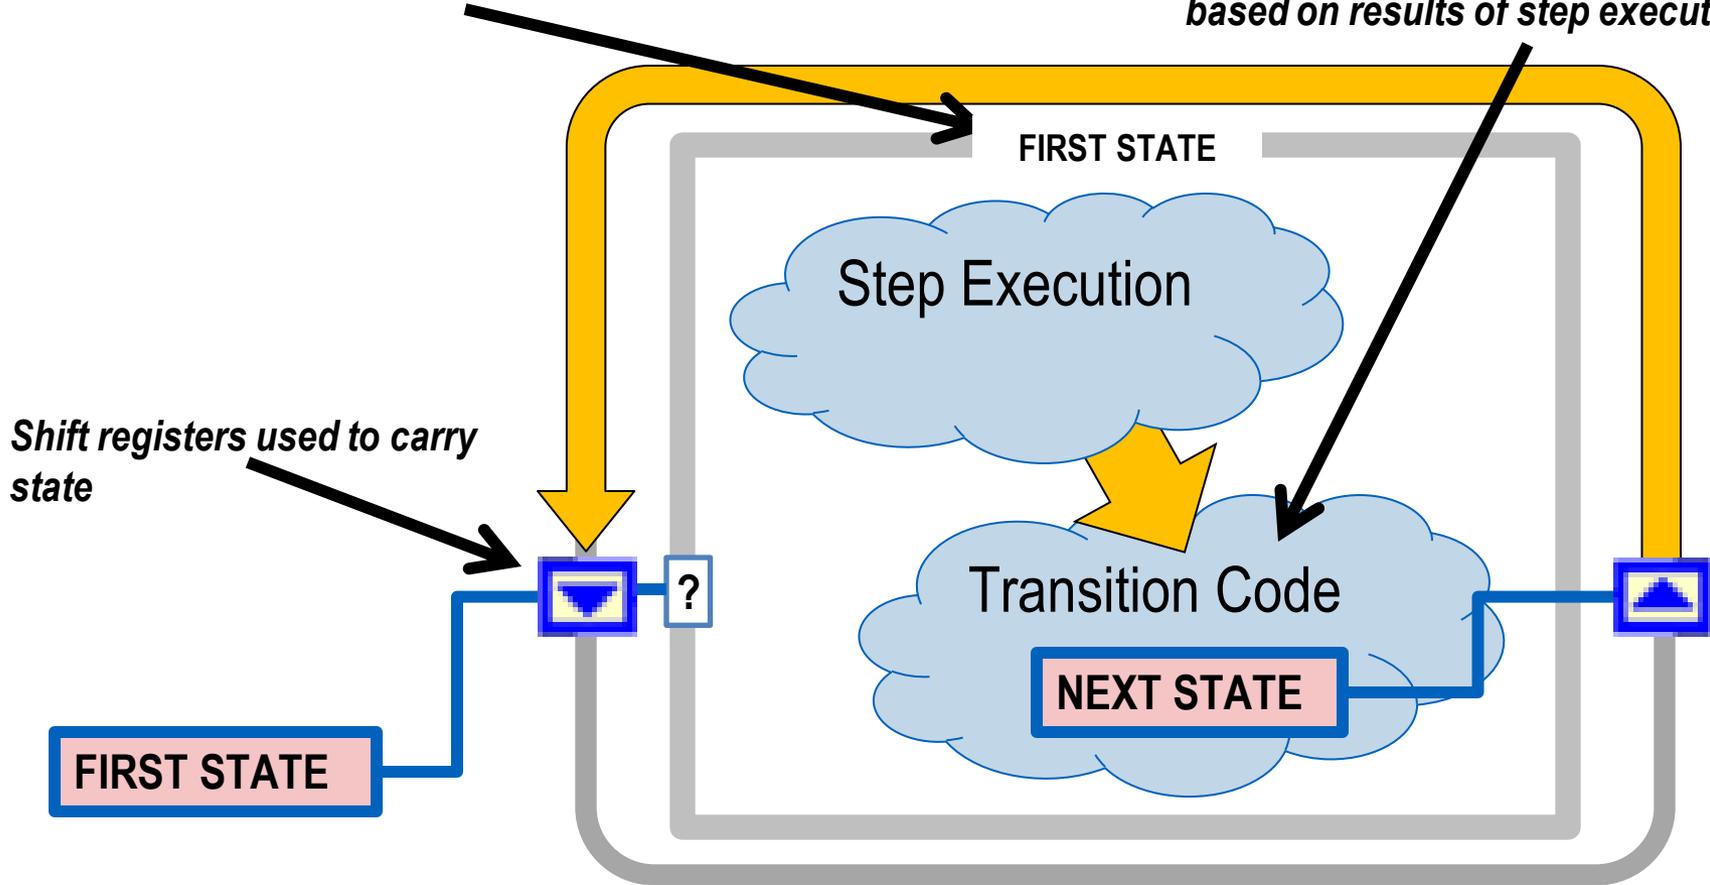

# Breaking Down the Design Pattern

- Case Structure inside of a While Loop
- Each case is a state
- Current state has decision making code that determines next state
- Use enumerators to pass value of next state to shift registers

# The Anatomy of a State Machine

*Case structure has a case for every state*

*Transition code determines next state based on results of step execution*

*Shift registers used to carry state*

FIRST STATE

FIRST STATE

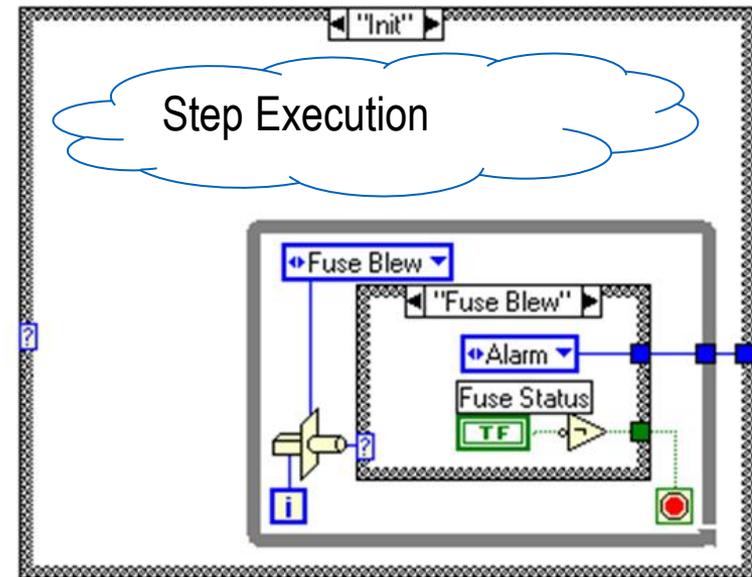

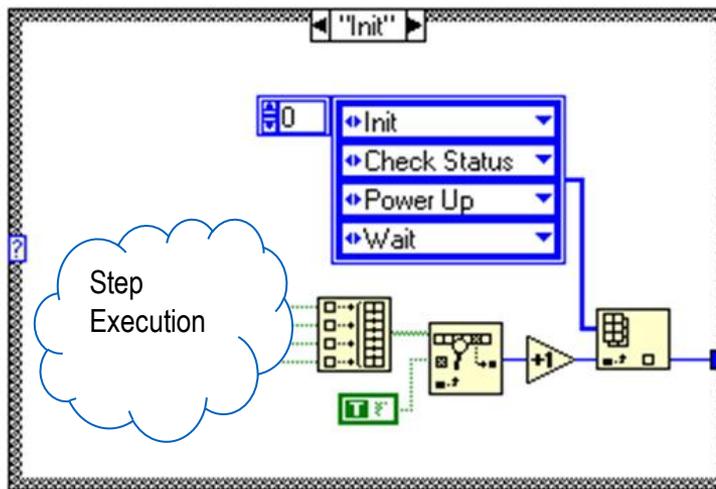

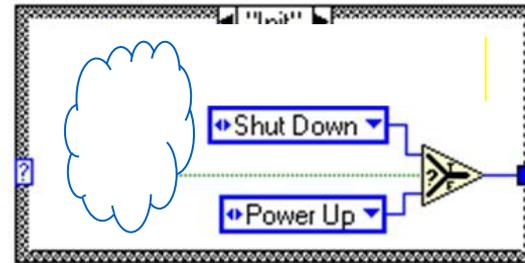

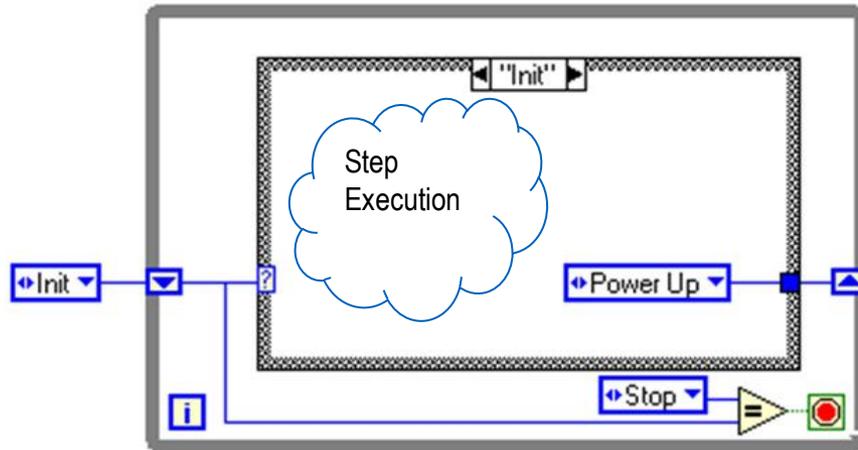

Step Execution

Transition Code

NEXT STATE

?

# Transition Code Options

State Machine

**DEMO**

# Recommendations

## Use Cases

- User interfaces
- Data determines next routine

## Considerations

- Creating an effective State Machine requires the designer to make a table of possible states.

# Event Driven User Interface

I'm polling for user actions, which is slowing my application down, and sometimes I don't detect them!

# Background

## Procedural-driven programming

- Set of instructions are performed in sequence
- Requires polling to capture events
- Cannot determine order of multiple events

## Event-driven programming

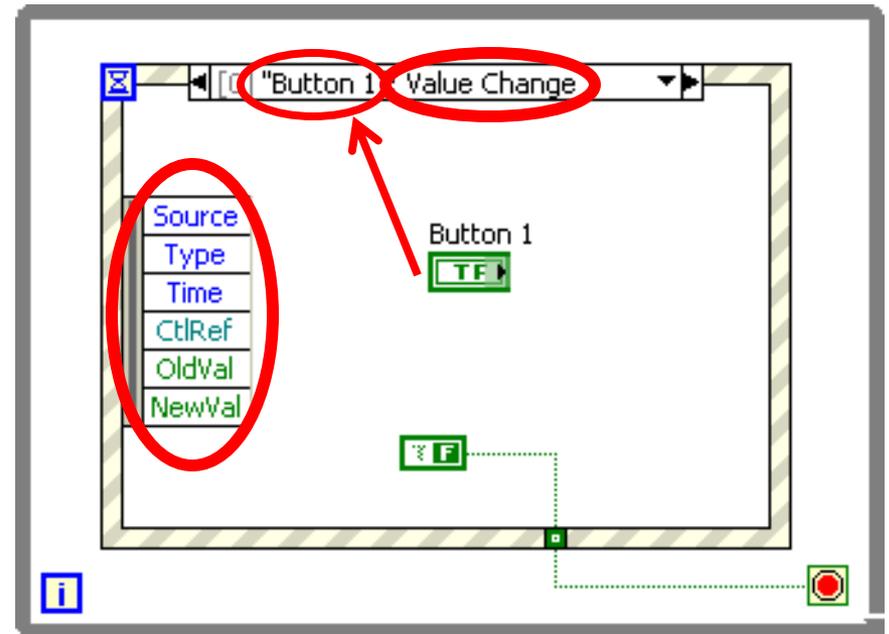

- Execution determined at run-time
- Waits for events to occur without consuming CPU
- Remembers order of multiple events

# Breaking Down the Design Pattern

- Event structure nested within loop
- Blocking function until event registered or timeout
- Events that can be registered:
  - Notify events are only for interactions with the front panel
  - Dynamic events allows programmatic registration
  - Filter events allow you to screen events before they're processed

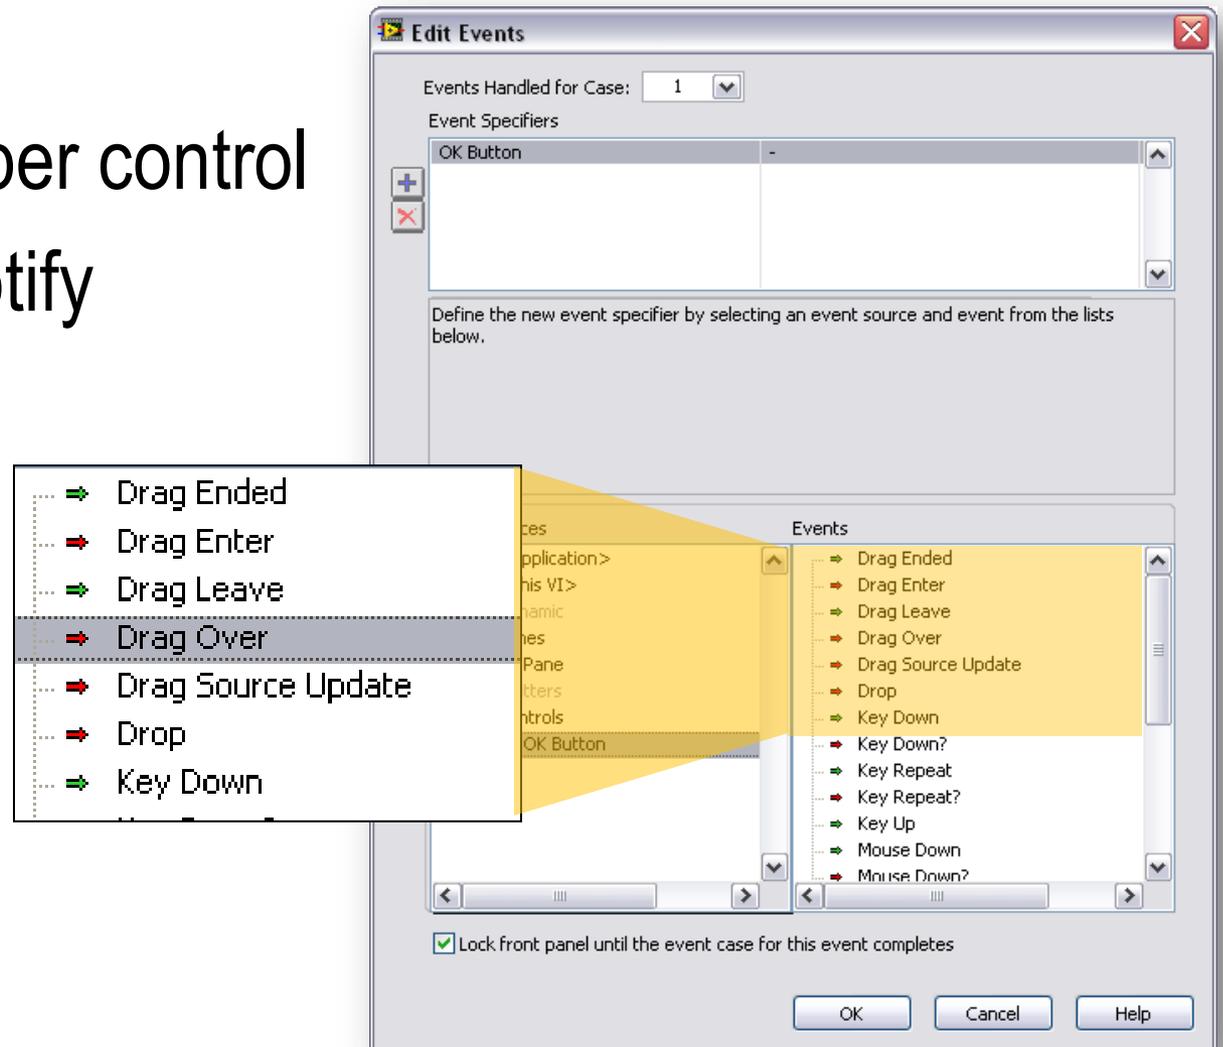

# How It Works

1. Operating system broadcasts system events (mouse click, keyboard, etc..) to applications
2. Registered events are captured by event structure and executes appropriate case
3. Event structure returns information about event to case
4. Event structure enqueues events that occur while it's busy

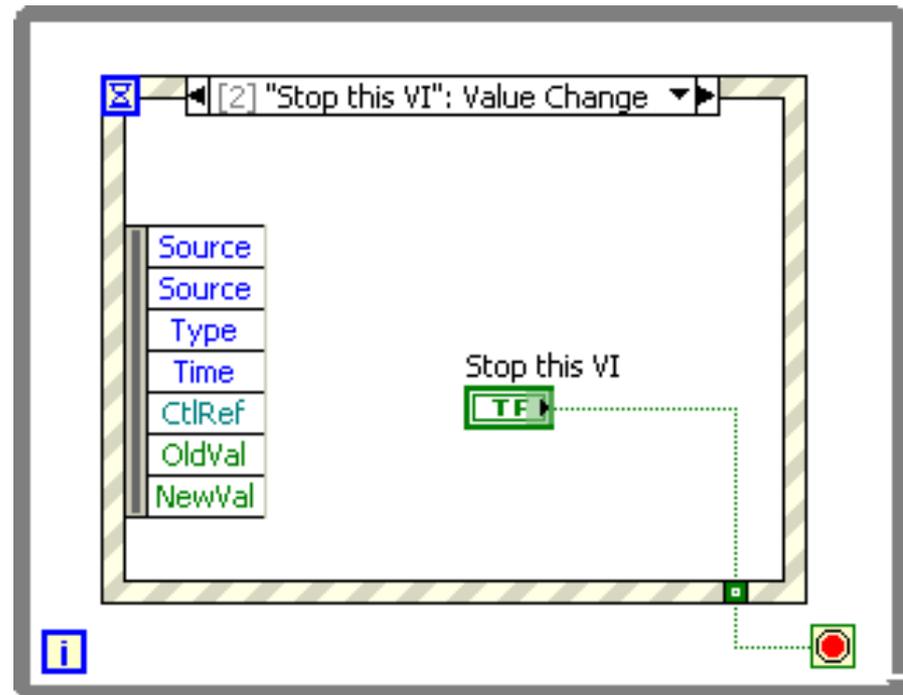

# How It Works: Static Binding

- Browse controls
- Browse events per control
- Green arrow: notify
- Red arrow: filter

Event Driven User Interface

# DEMO

# Recommendations

## Use Cases

- UI: Conserve CPU usage
- UI: Ensure you never miss an event
- Drive slave processes

## Considerations

- Avoid placing two Event structures in one loop
- Remember to read the terminal of a latched Boolean control in its Value Change event case
- When using subpanel controls, the top-level VI containing the subpanel control handles the event

# Producer / Consumer

I have two processes that need to execute at the same time,  
and I need to make sure one can't slow the other down

# Background

I want to execute code in parallel and at asynchronous rates, but I need to communicate between them!

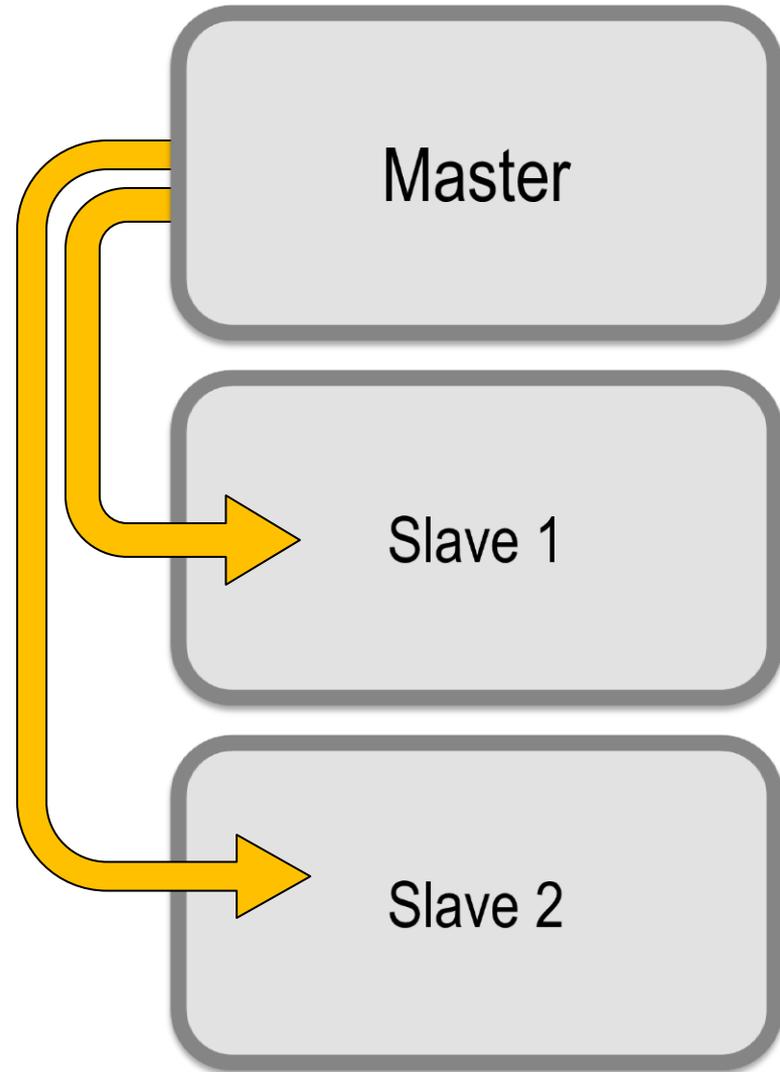

I have two processes that need to execute at the same time, but I want them to be independent of one another, and I need to make sure one can't slow the other down

# Breaking Down the Design Pattern

- Data independent loops
- Master / slave relationship
- Communication and synchronization between loops

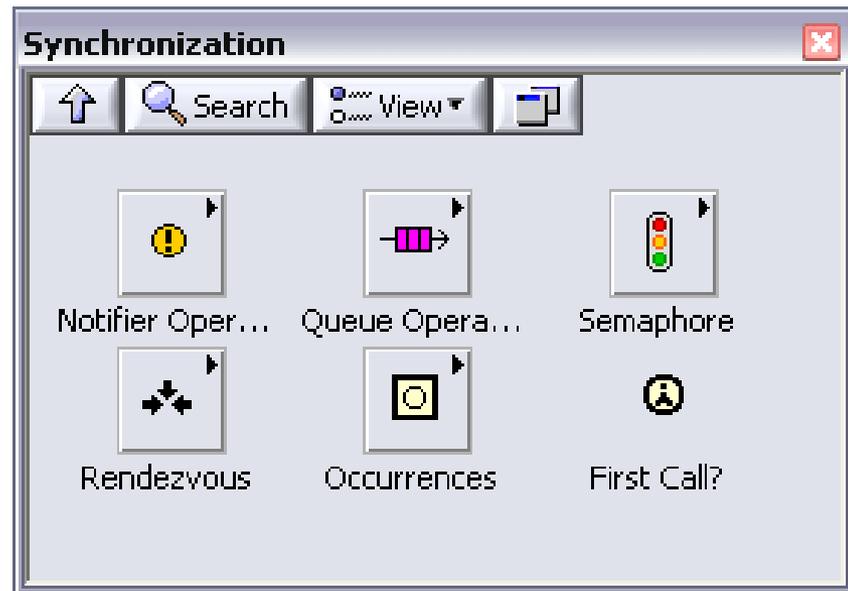

# How It Works

- One or more slave loops are told by a master loop when they can run
- Allows for a-synchronous execution of loops
- Data-independence breaks dataflow and allows multi-threading
- De-couples processes

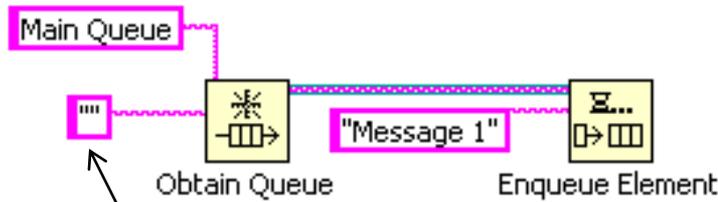

# Master / Slave: Loop Communication

- Variables
- Occurrences
- Notifier
- Queues
- Semaphores
- Rendezvous

# Queues

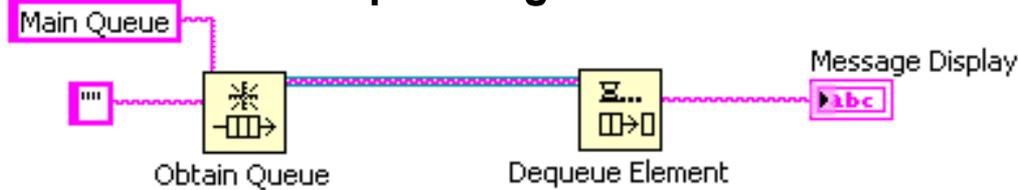

## Adding Elements to the Queue

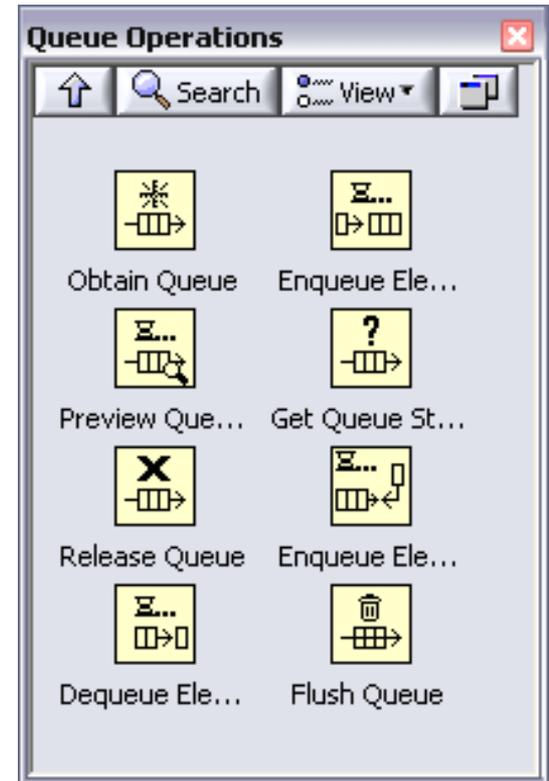

Select the data-type the queue will hold

Reference to existing queue in memory

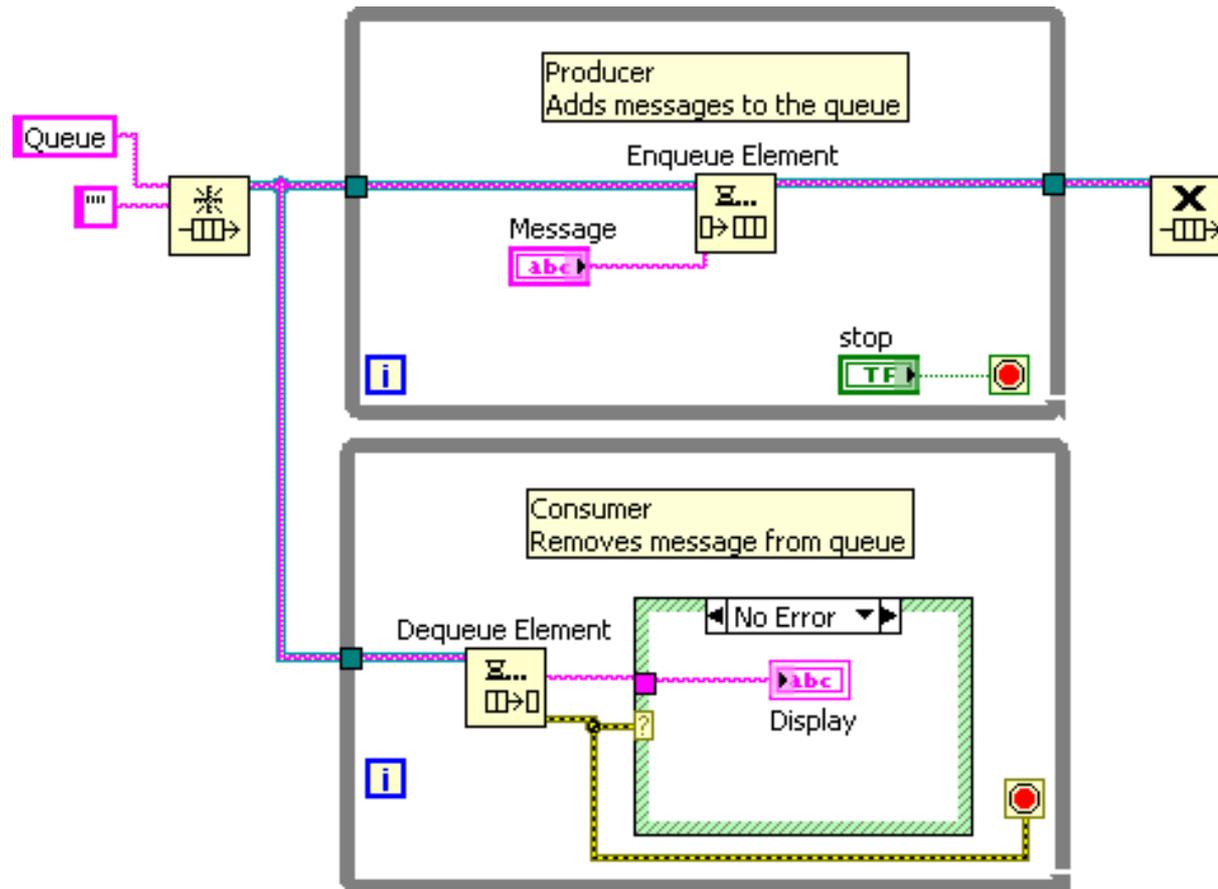

## De-queueing Elements

Dequeue will wait for data or timeout (defaults to -1)

# Producer / Consumer

Producer / Consumer

**DEMO**

# Recommendations

## Use cases

- Handling multiple processes simultaneously
- Asynchronous operation of loops

## Considerations

- Multiple producers → One consumer
- One queue per consumer
- If order of execution of parallel loop is critical, use occurrences

# Queued State Machine & Event-Driven Producer / Consumer

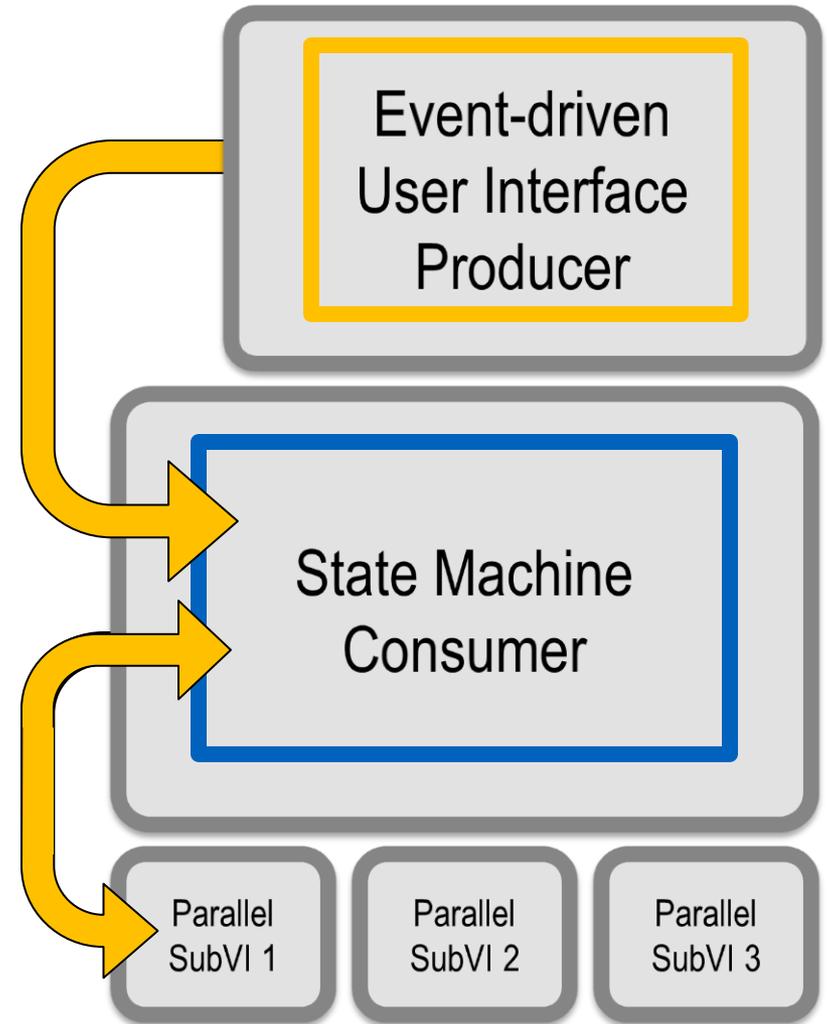

I need to enqueue events from a user that control the sequence of events in a consumer loop

# Breaking Down the Design Pattern

- Event-driven user interface design pattern
- State machine design pattern
- Producer consumer design pattern
- Queued communication between loops

# How It Works

1. Events are captured by producer
2. Producer places data on the queue
3. State machine in consumer executes on dequeued data
4. Parallel SubVIs communicate using queue references

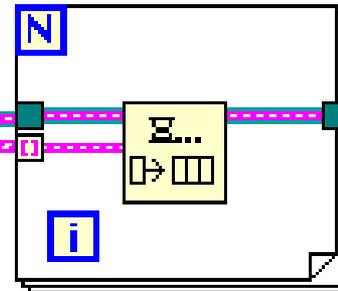

# Queues Recommendations

Use a cluster containing an enum and variant as data-type

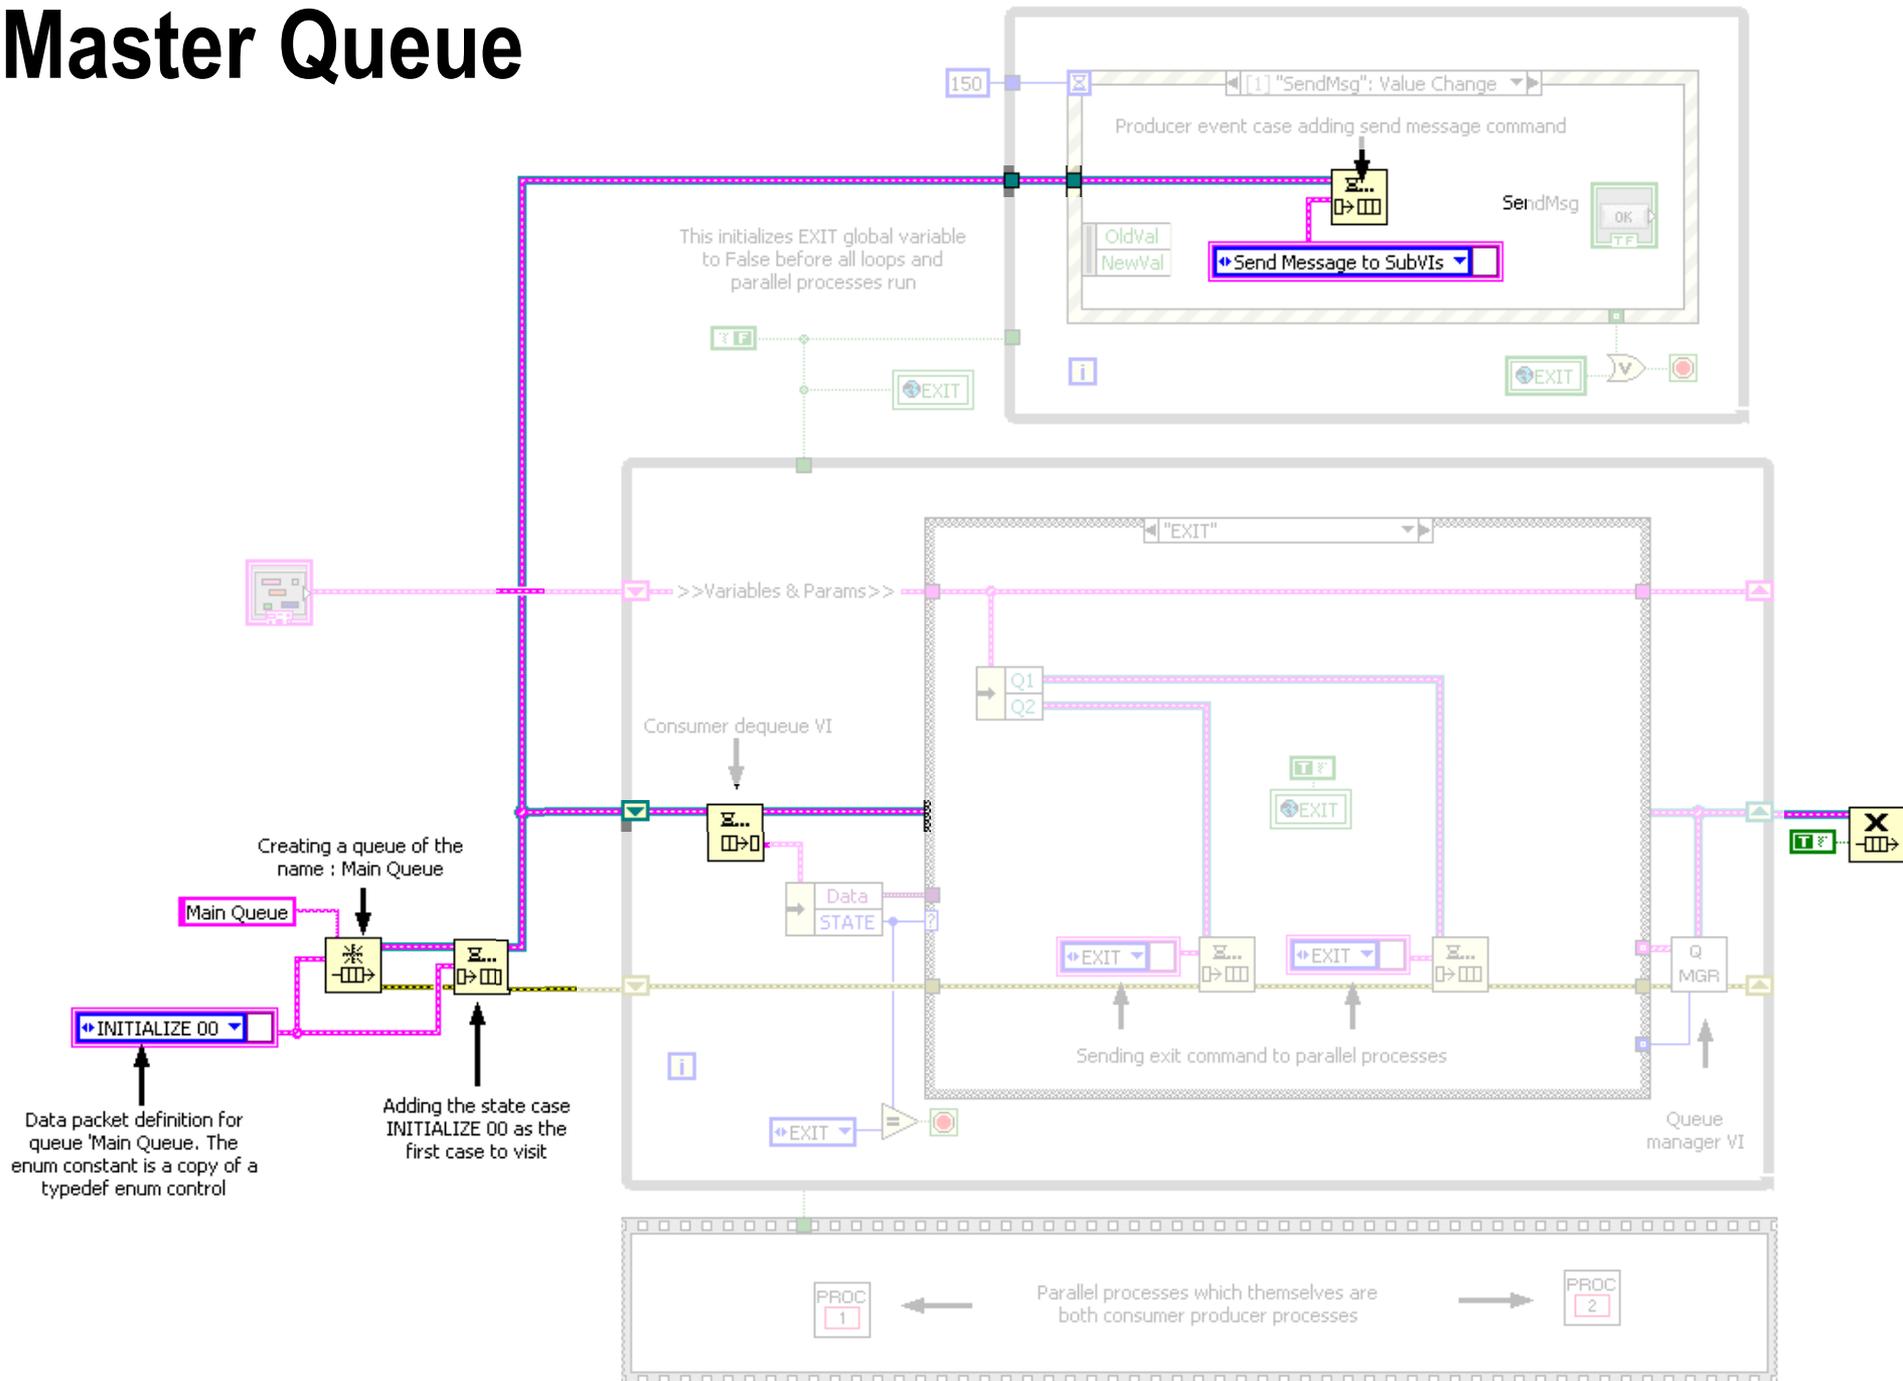

Refer to queues by name for communication across VIs

# Master Queue

Data packet definition for queue 'Main Queue'. The enum constant is a copy of a typedef enum control

Creating a queue of the name : Main Queue

Main Queue

Adding the state case INITIALIZE 00 as the first case to visit

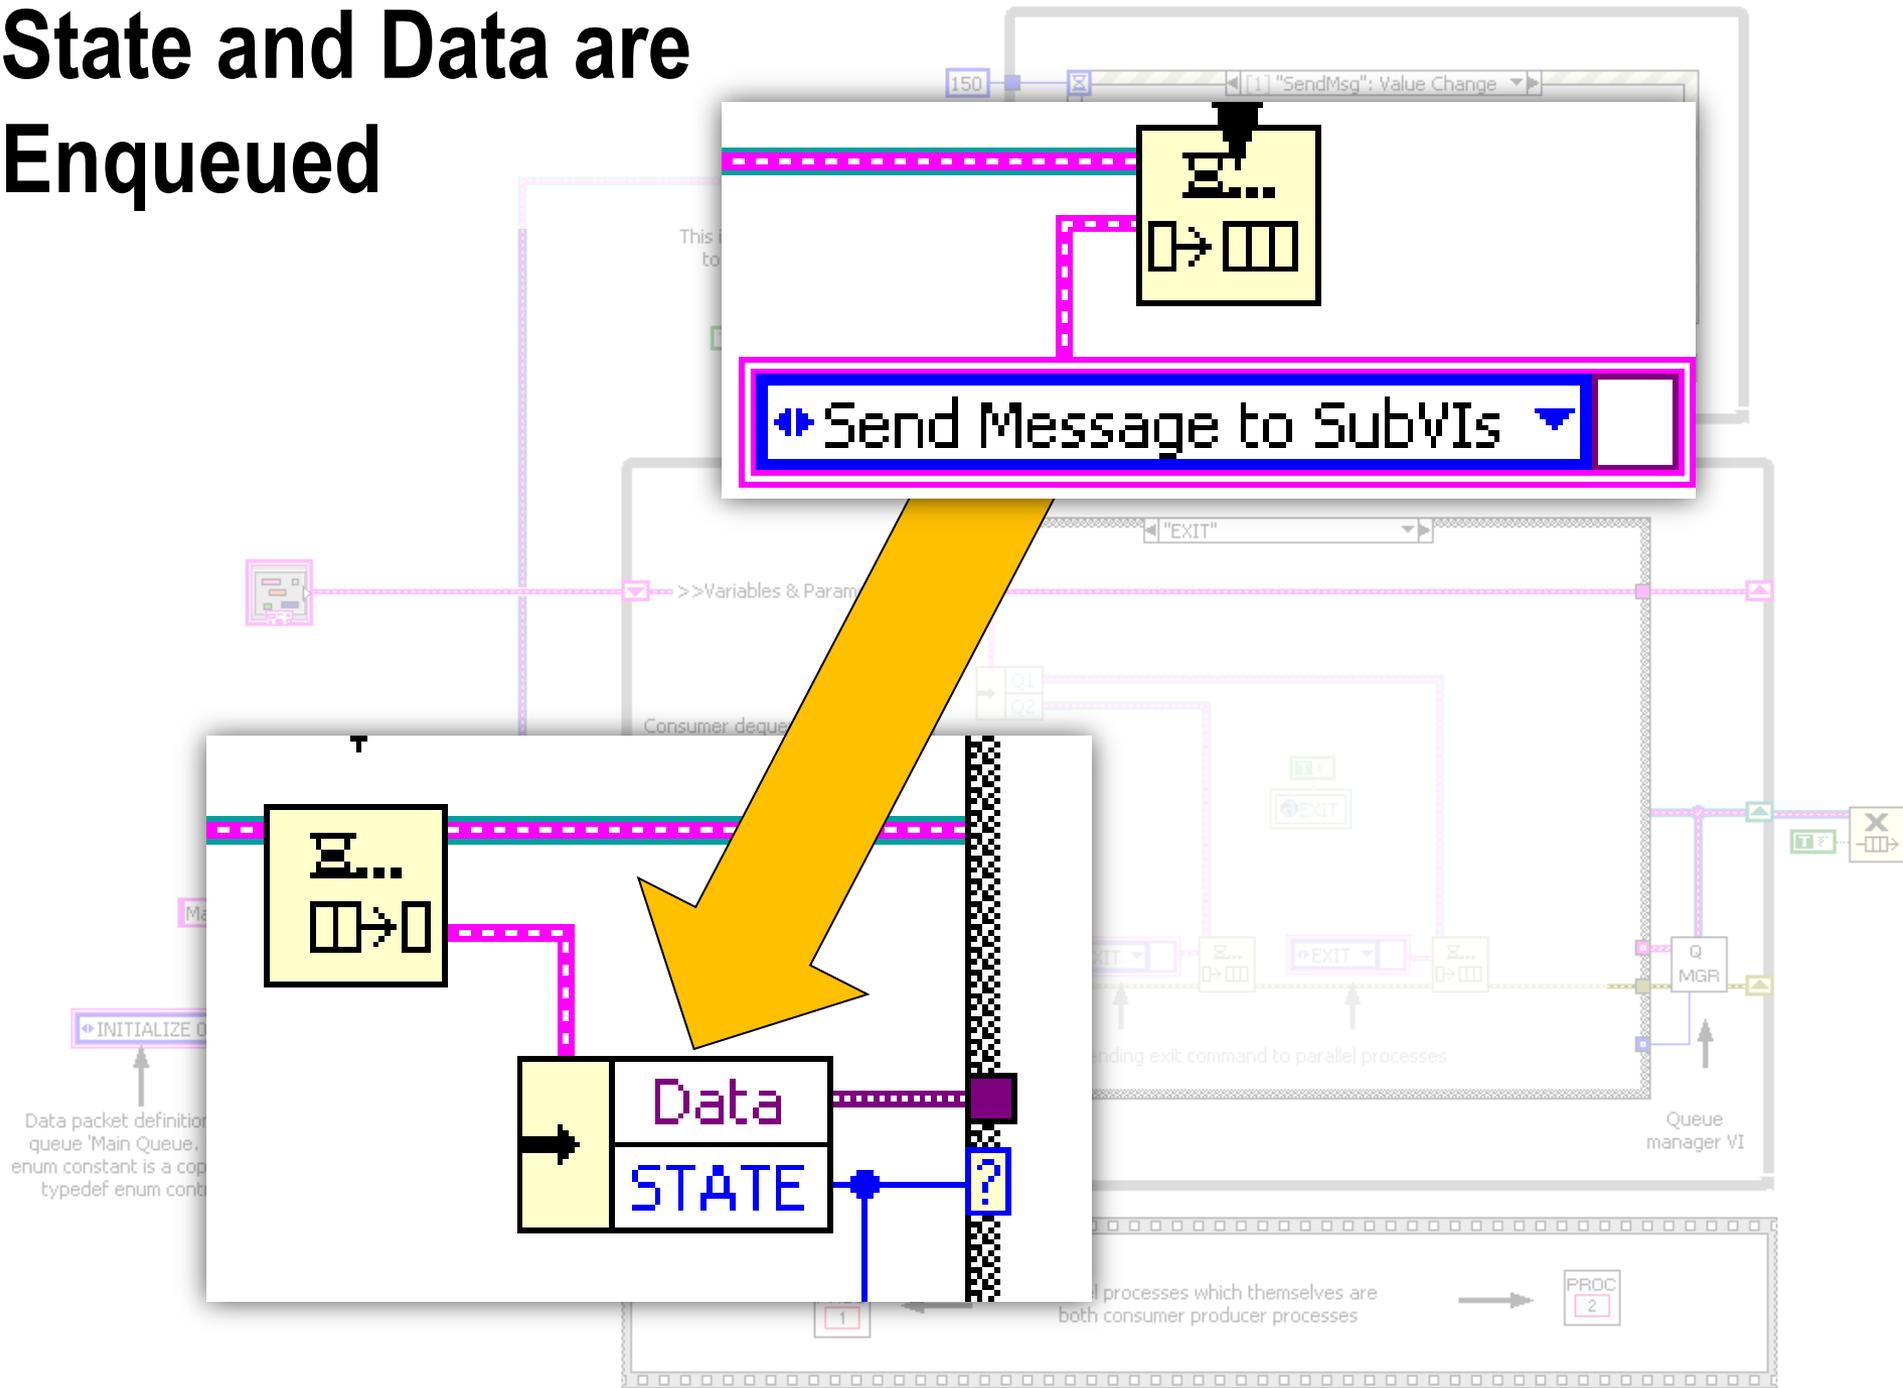

This initializes EXIT global variable to False before all loops and parallel processes run

Sending exit command to parallel processes

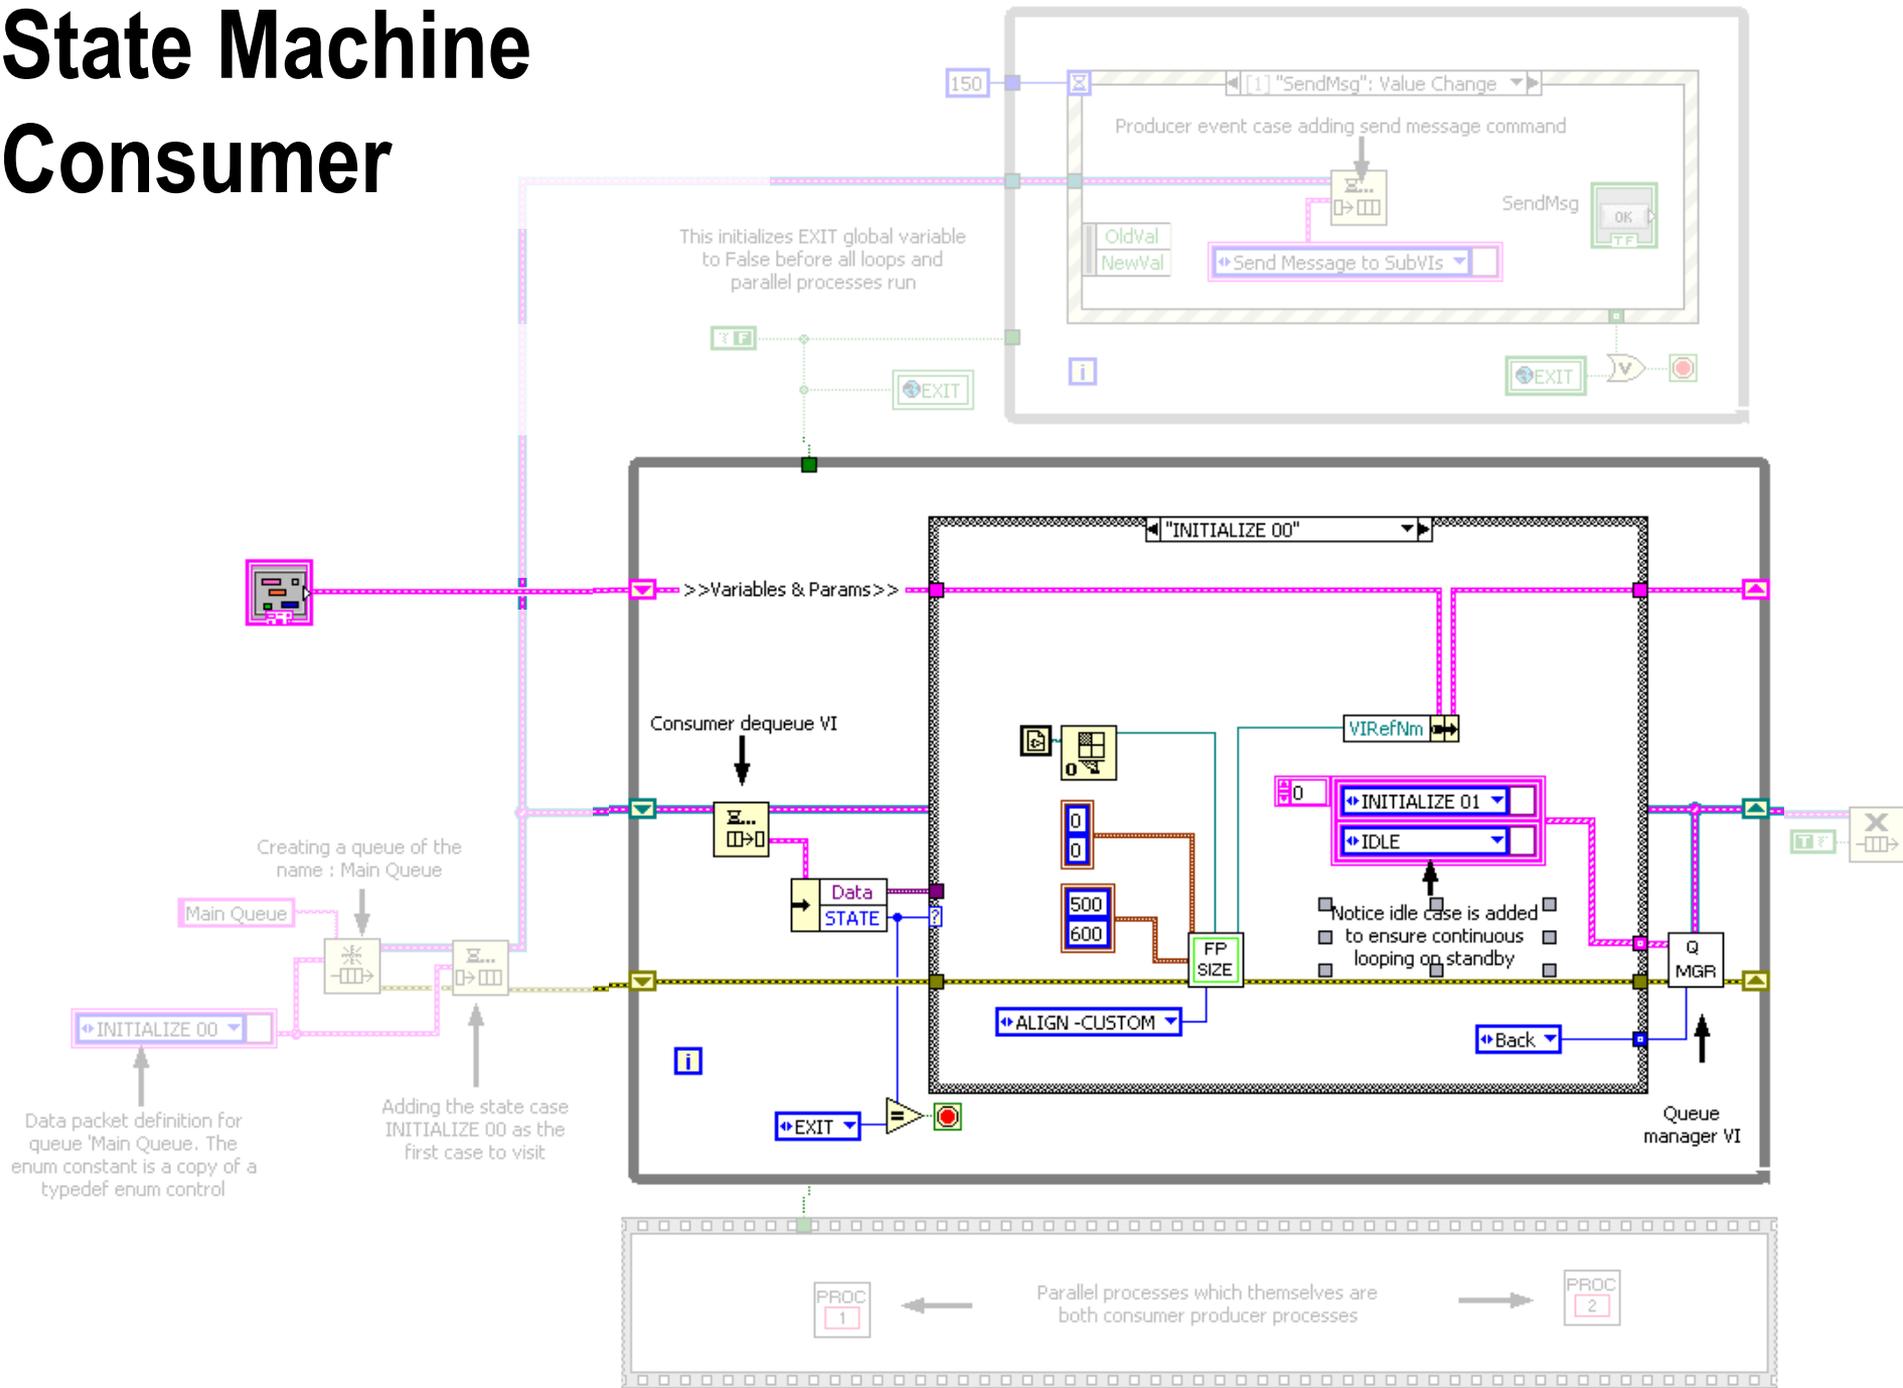

Parallel processes which themselves are both consumer producer processes

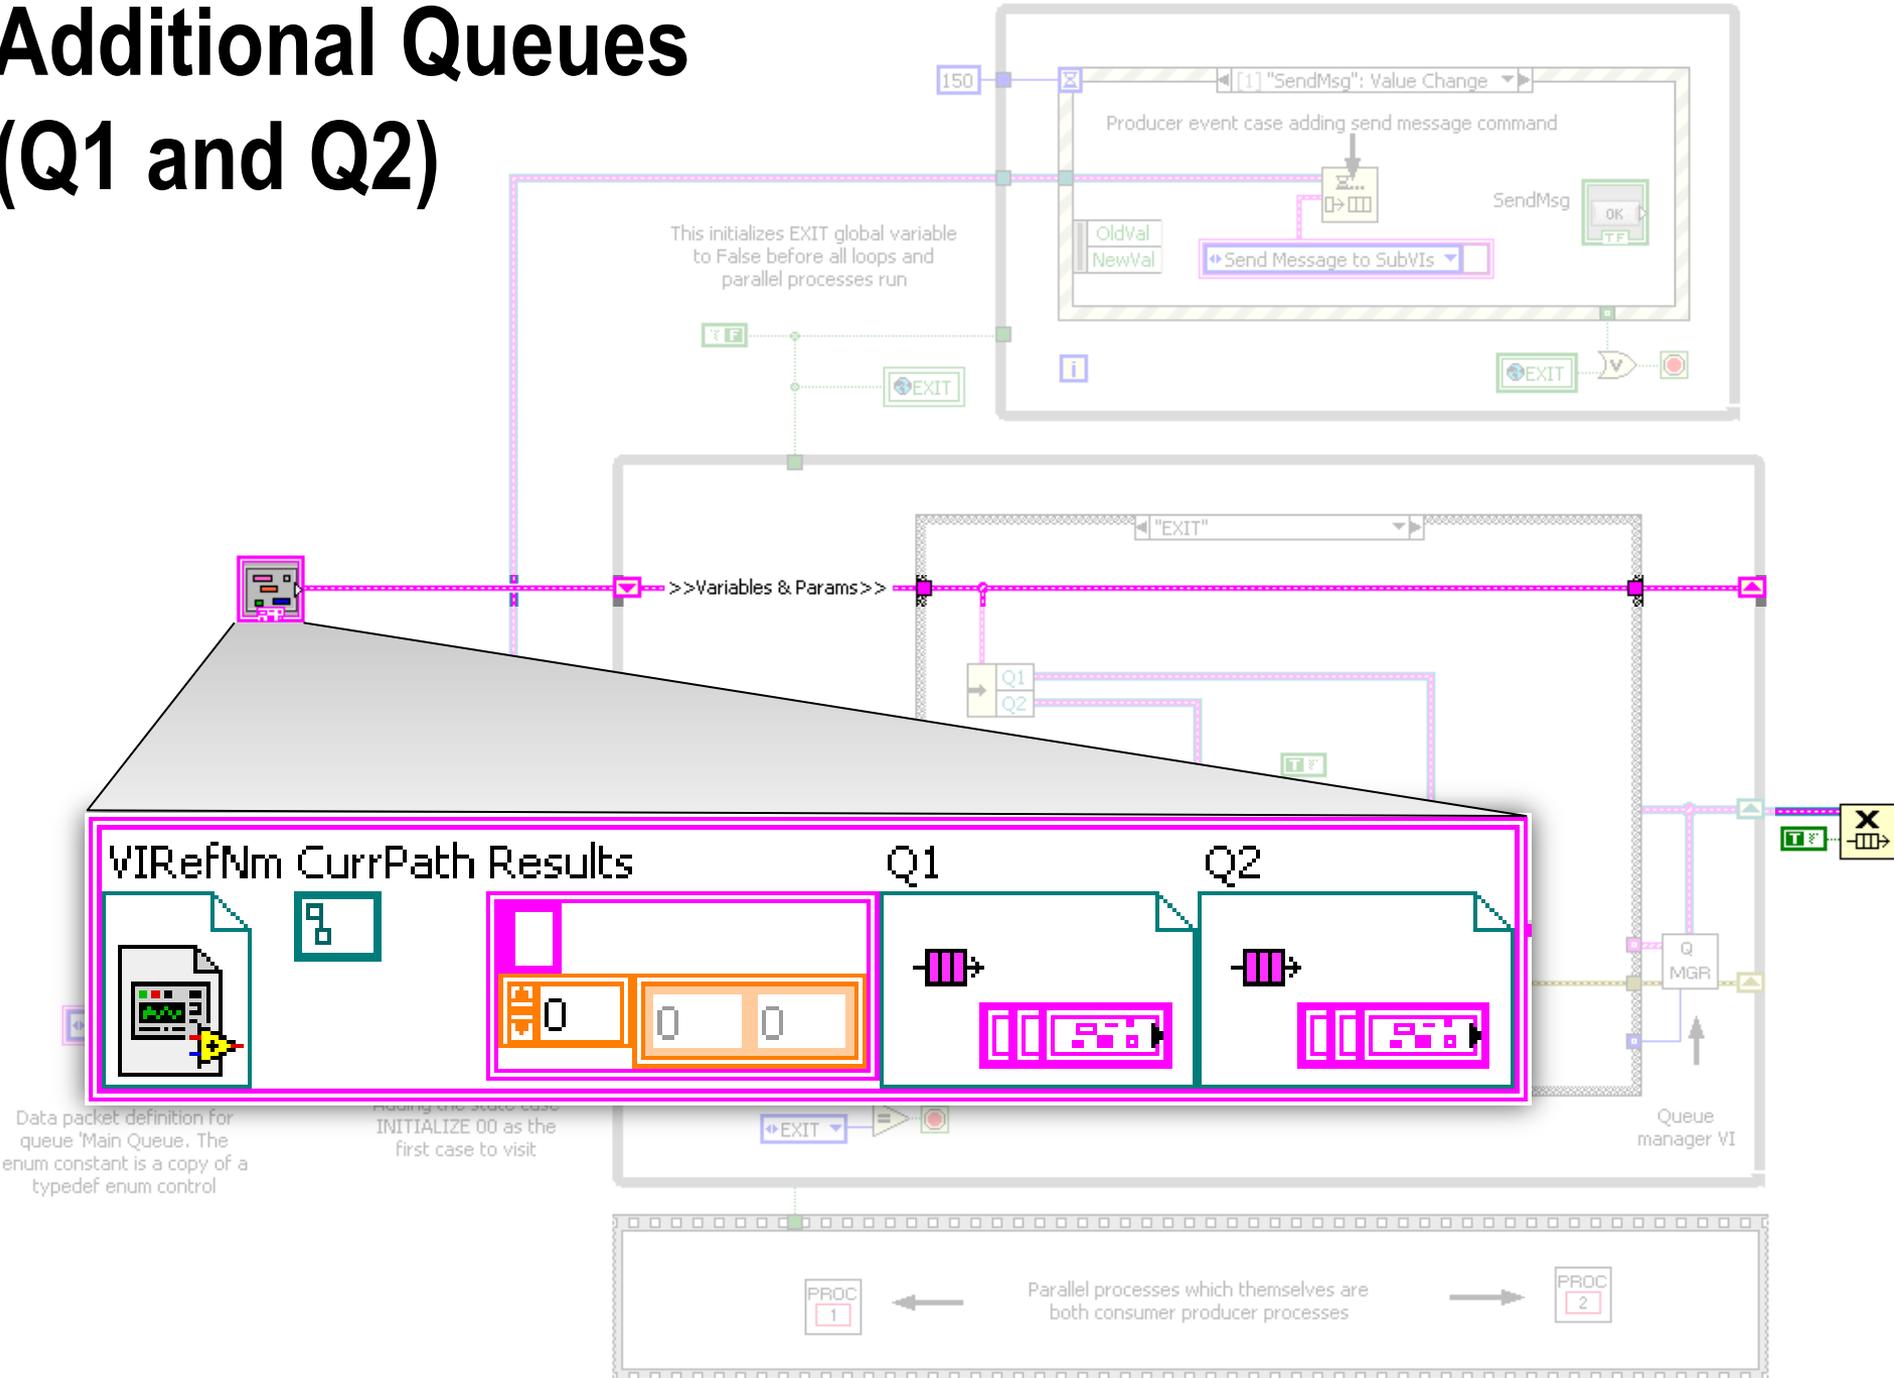

# State and Data are Enqueued

# State Machine Consumer

# Additional Queues (Q1 and Q2)

This initializes EXIT global variable to False before all loops and parallel processes run

>>Variables & Params>>

VIRefNm CurrPath Results

Q1

Q2

0 0 0

0 0 0

0 0 0

Data packet definition for queue 'Main Queue'. The enum constant is a copy of a typedef enum control

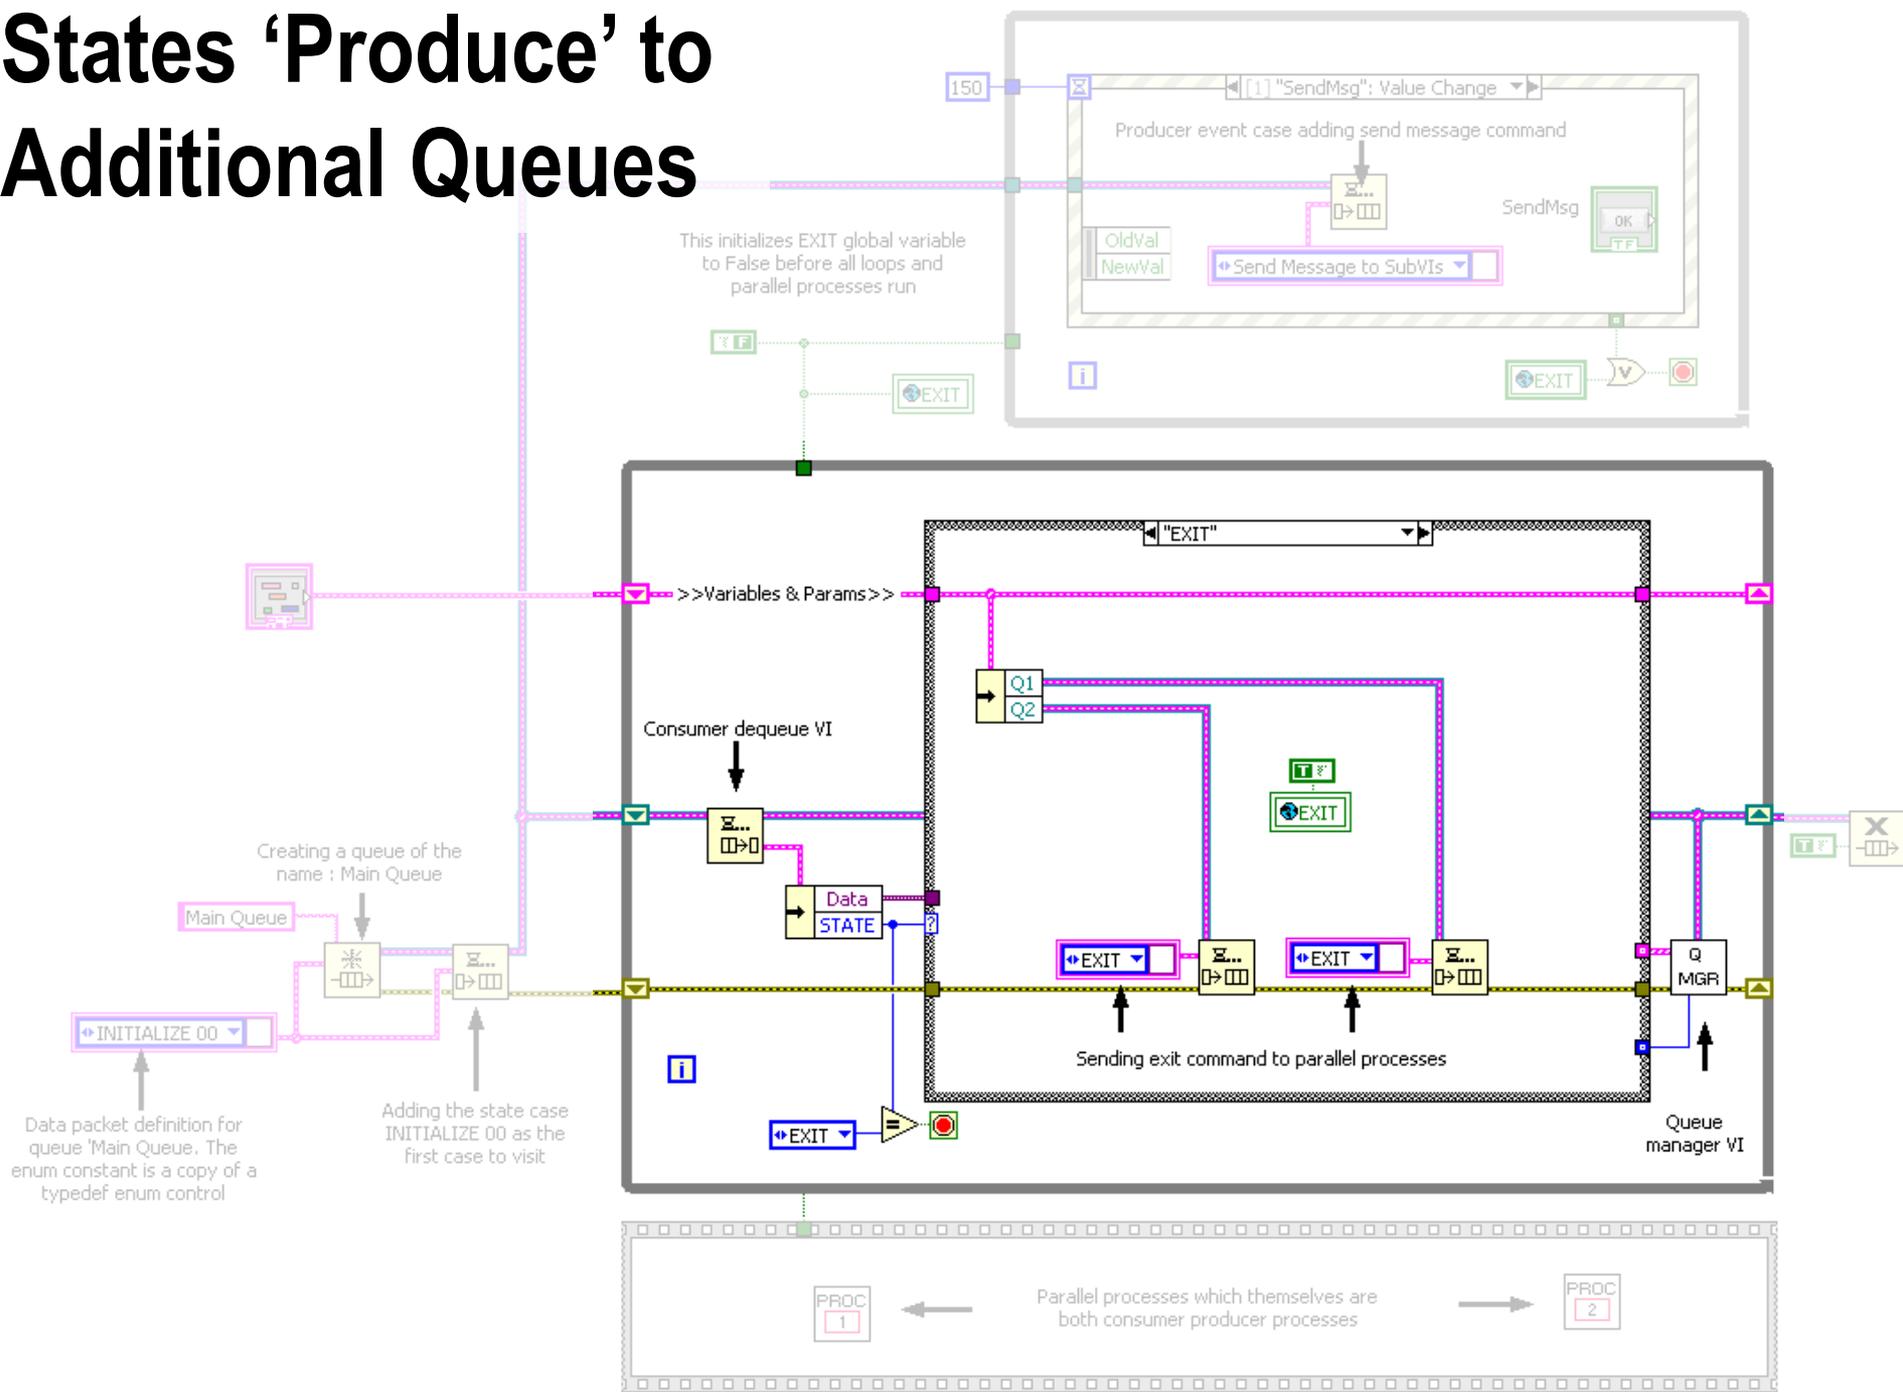

Adding the state case INITIALIZE 00 as the first case to visit

PROC 1

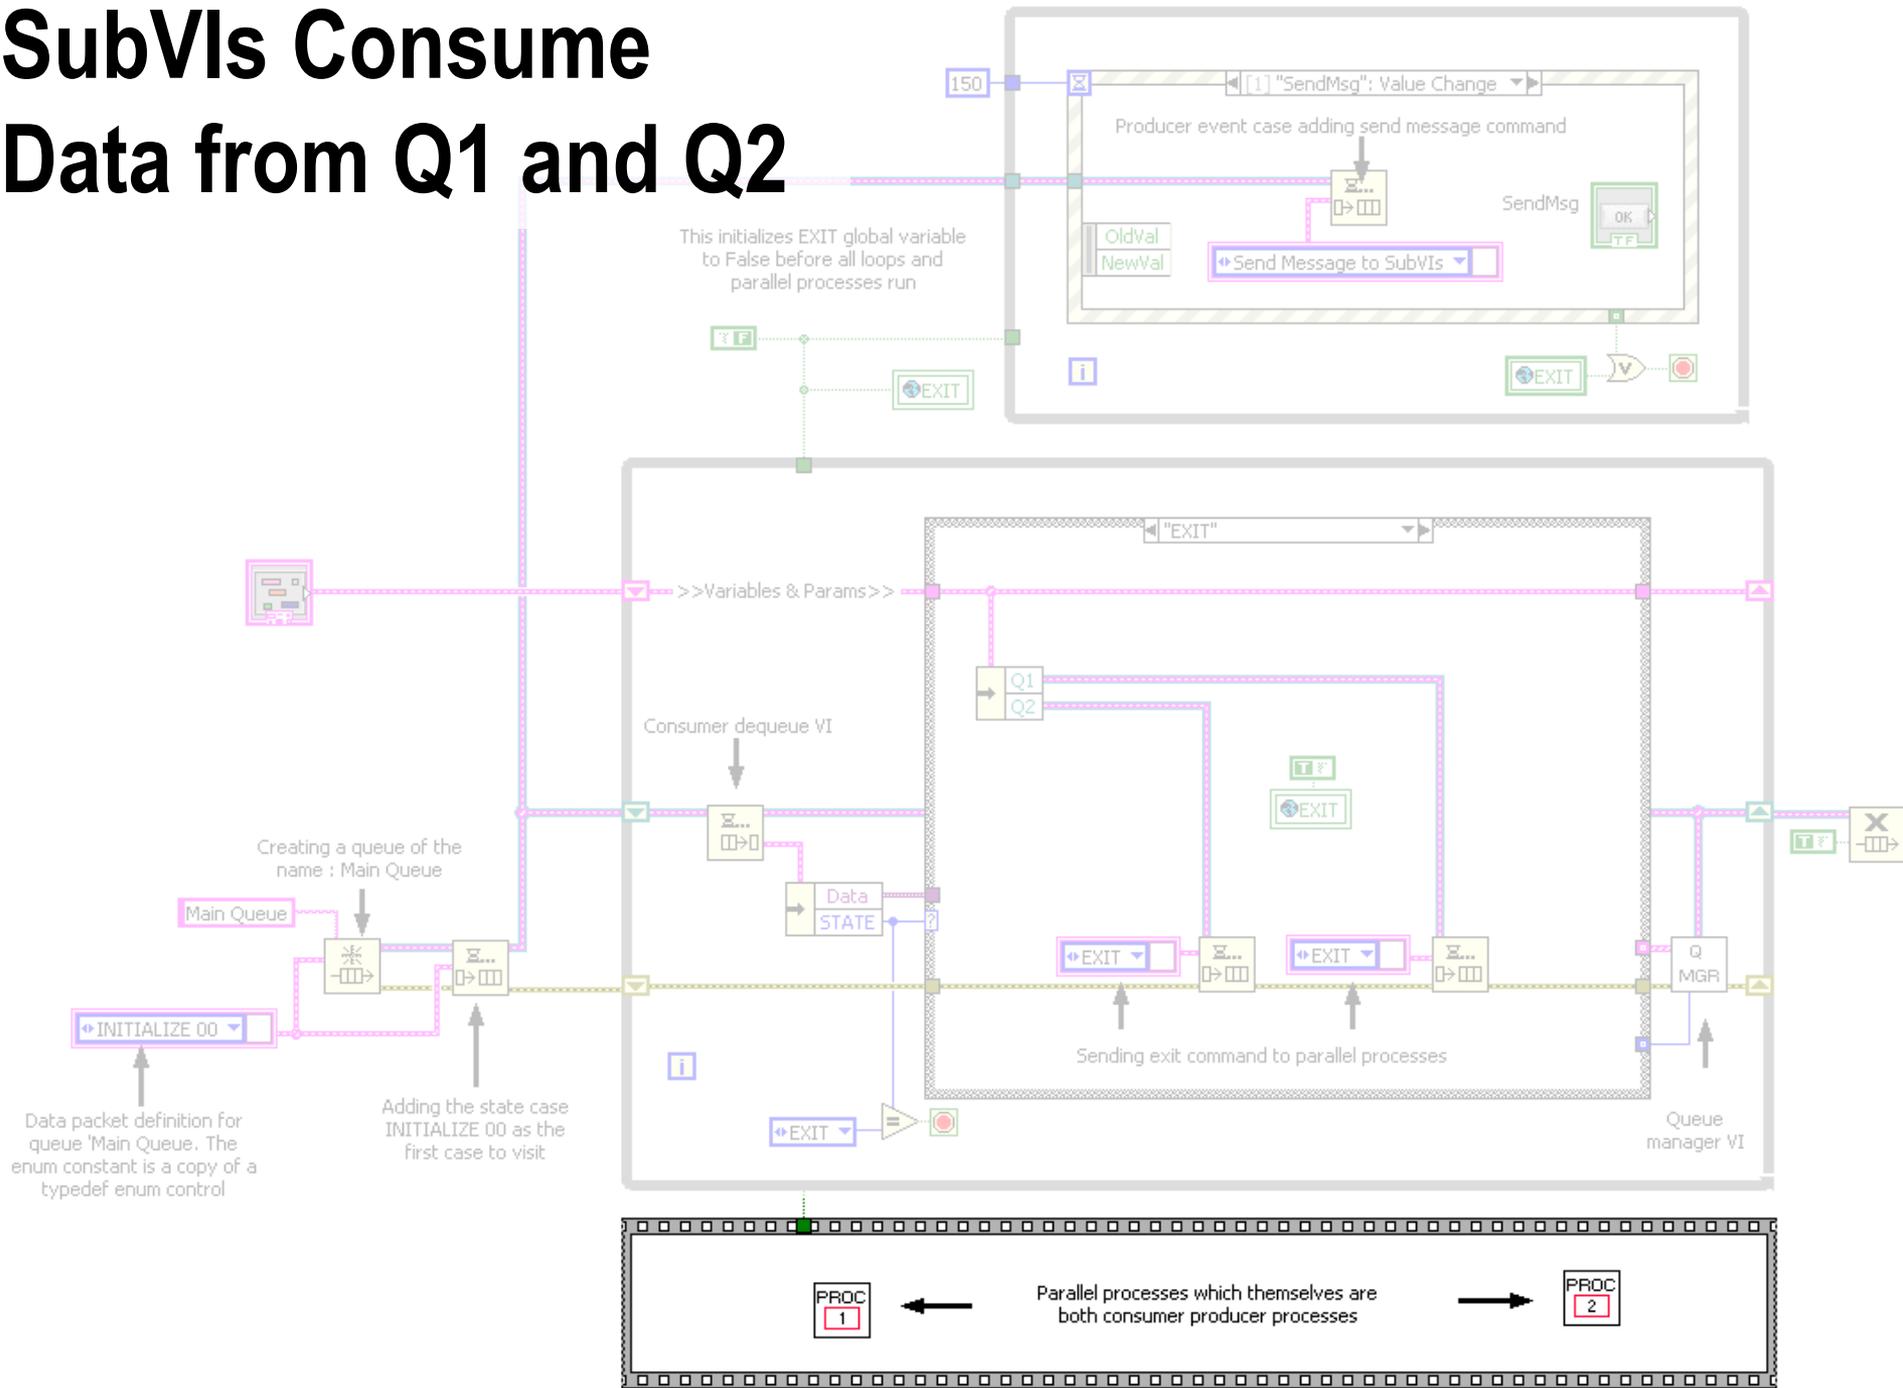

Parallel processes which themselves are both consumer producer processes

PROC 2

# States 'Produce' to Additional Queues

# SubVIs Consume Data from Q1 and Q2

Queued State Machine – Producer/Consumer

**DEMO**

# Recommendations

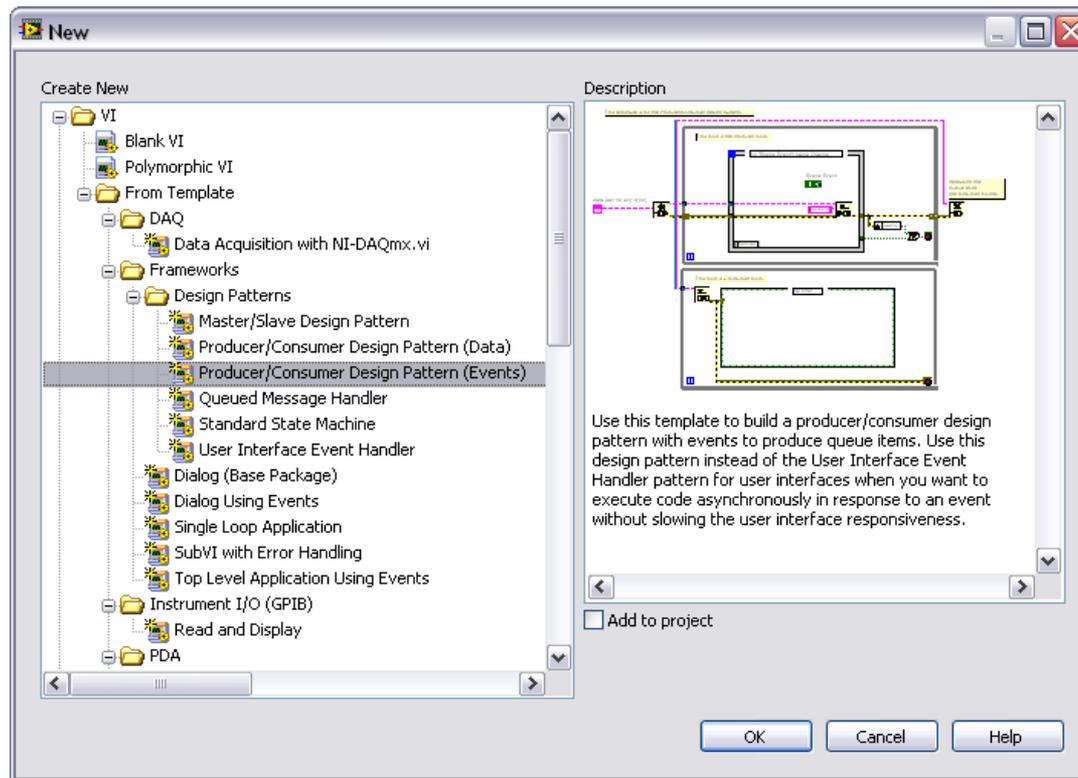

## Use Cases

- Popular design pattern for mid to large size applications
- Highly responsive user interfaces
- Multithreaded applications
- De-coupling of processes

## Considerations

- Complex design
